Dear Mr. Landis:

Your urine sample collected at the Tour de France on July 20, 2006, was sent to the WADA accredited laboratory at Chateau-Malabry, France, ("the Laboratory") for analysis. The Laboratory has reported that your A sample contains an elevated testosterone/epitestosterone (T/E) ratio at a prohibited level of greater than 4:1. Additionally, the laboratory performed a Carbon Isotope Ratio (CIR) analysis on your sample and reported the result positive for exogenous testosterone or its precursors. The World Anti-Doping Agency's Prohibited List, adopted by both the USADA Protocol for Olympic Movement Testing ("Protocol") and the Union Cycliste Internationale ("UCI") Anti-Doping Rules, lists testosterone and its precursors as prohibited substances in the class of anabolic androgenic steroids.

I have enclosed the July 26, 2006, letter from UCI and the documents attached to that letter, including the Laboratory's report, referring your case. On July 26, 2006, USA Cycling forwarded the UCI documents to USADA and in accordance with the rules requested that USADA handle the adjudication of this matter. I have also enclosed a copy of this correspondence from USA Cycling to USADA and USADA's response of today to USA Cycling formally accepting the handling of your case.

As referenced in the UCI letter dated July 26, 2006, in accordance with UCI rules you must immediately request, without delay, the B sample analysis or the B sample analysis will be deemed waived and the laboratory results conclusively established. In accordance with UCI rule 194, the request for the analysis of the B sample must be made no more than five (5) working days from July 26, 2006, the date of the UCI letter. Please inform me immediately in writing by fax at 719-785-2028 if you elect to have the B opening and analysis performed and we will notify the Laboratory and UCI of your request and attempt to schedule the date for the B analysis. You also

GDC0001

have the right to attend the B sample opening and analysis if requested (which may take many hours, over multiple days).

Further, if you choose not to request the B sample analysis, USADA will forward your case immediately to a panel of the independent USADA Anti-Doping Review Board, as set forth in the USADA Protocol, for its consideration. Under the USADA Protocol and the UCI Anti-Doping Rules, the finding of a prohibited substance or method in an athlete's sample constitutes a doping violation. If it is ultimately determined that this is your first doping violation, a sanction may be imposed that will include disqualification of your competitive results achieved on and subsequent to July 20, 2006, the day your sample was collected, and up to a two year period of ineligibility.

Additionally, you have the right, at this time, to accept a "provisional suspension." By accepting a "provisional suspension," you will be immediately suspended from competing in all competitions under the jurisdiction of UCI, USA Cycling, and the United States Olympic Committee ("USOC"), or any of these entities' clubs, member associations or affiliates, until your case is deemed not to be a doping offense, you accept a sanction, you fail to contest this matter, or a hearing has been held in this matter. If you choose to accept this "provisional suspension," the time served under the "provisional suspension" will be deducted from any period of ineligibility that you might receive beginning on the date you accept the "provisional suspension" and notify USADA of such acceptance. If you do not to execute and return this "provisional suspension," any period of ineligibility you might receive will begin on the date of your acceptance of the sanction or on the date of the arbitration hearing panel's decision.

If you execute and return the "provisional suspension," USADA will give notice to the USOC, UCI, and USA Cycling of your acceptance of the "provisional suspension." Your decision to accept this "provisional suspension" is purely optional. You do not have to accept this "provisional suspension" in order to proceed with your case. If you are willing to accept a "provisional suspension," please inform us in writing immediately, by executing and returning the attached USADA Acceptance of Provisional Suspension Form.

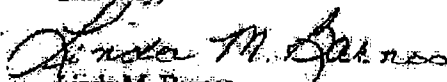

If you intend to compete in any protected competitions, USADA has the right under its Protocol, Section 13, to expedite this matter to final resolution prior to the protected competition.

Also of importance, you are still subject to testing pending the outcome of this matter.

USADA will not publicly disclose or comment on the specifics of your test results until your case has been resolved. By copy of this letter, USADA is notifying USA Cycling and the USOC of your test results and requests that these organizations not comment publicly concerning this information until disclosed as provided in the USADA Protocol.

Enclosed for your reference are copies of the USADA Protocol, UCI Anti-Doping Rules and the World Anti-Doping Code, which set forth the administrative procedures followed for positive and elevated tests and other alleged anti-doping rule violations. You may also wish to contact John Ruger, the USOC Athlete Ombudsman who is completely independent of USADA, or your own personal attorney, for assistance or further information. Mr. Ruger may be reached at One Olympic Plaza, Colorado Springs, CO, 80909, by telephone at (888)-ATHLETE, by fax at (303) 444-6626 or by e-mail at John.Ruger@usoc.org, or at www.888athlete.org.

Sincerely,

Linda M. Barnes
Testing Results Manager

31st July 2006

Dear Sir:

I have received on the 26th July from my legal PHONAK HEARING SYSTEMS copy of a letter sent by UCI that same day concerning my testing positive (T/F) in the Tour de France on the eve of the 26th July.

By means of this letter:

- (i) I formally require the B sample analysis in accordance with articles 191 and following of the Anti-Doping Rules (ADR).
- (ii) I appoint as my legal representatives, Mr Luis Saez Hernández and Mr José M. Buxeda Malaterra, lawyers in Madrid (Spain). I request that any formal communication concerning this issue is sent to the latter (Mr José M. Buxeda, MASONS BUXEDA MENCHEN ABOGADOS, Calle José Ortega y Gasset, nº 25, 28006 - Madrid, T +34 914363329, F +34 914363729, e-mail: masonsbuxeda@masonsbuxeda.com). According to article 193 ADR, they will attend the opening of sample B.
- (iii) I appoint as the person that will attend the sample B analysis on my behalf, Dr Deuse de Roer, Department of Clinical Chemistry, University Hospital Maastricht.
- (iv) I require a copy of the complete analysis report for sample A that should be sent to my legal representatives as soon as possible.

The UCI communicates that the analysis of the sample B of Floyd Landis's urine has confirmed the result of an adverse analytical finding notified by the Anti-doping laboratory of Paris on 26th July, following the analysis of the sample A.

In accordance to the Anti-doping rules, the Anti-doping Commission of the UCI will request that the USA Cycling Federation open a disciplinary procedure against the rider.

Attorneys for Floyd Landis

UNITED STATES ANTI-DOPING AGENCY
INDEPENDENT ANTI-DOPING REVIEW BOARD

In The Matter Of
FLOYD LANDIS

SUBMISSION TO USADA INDEPENDENT ANTI-DOPING REVIEW BOARD

I. INTRODUCTION

This matter arises from the alleged positive drug test of Floyd Landis at the Tour de France on July 20, 2006. Mr. Landis allegedly tested positive for exogenous testosterone. Floyd Landis vehemently denies the allegations being made in this case.¹

This submission is made without access to complete documentation, and without access to any documents that would be required in any longitudinal study of

¹ While USADA may have redacted the name "Floyd Landis" in the documents provided to this Review Board, Landis will not participate in the charade that this is a confidential proceeding for two primary reasons: (1) given the improper leak and press statements by the UCI, the entire free world is aware that Floyd Landis, the 2006 Tour de France Champion, provided the only positive urine sample that is being pursued through disciplinary proceedings as a result of the 2006 Tour de France; and (2) the August 30, 2006 cover letter from USADA to the Review Board, which states "Re: UCI File No. 29/06, Tour de France, July 20, 2006," destroys any confidentiality in this specific proceeding given point (1) above.

testosterone/epitestosterone values. This submission should not be considered in any respect to be a complete recitation of the defenses that may be offered by or on behalf of Floyd Landis, and Floyd Landis specifically reserves the right to make any submission to any adjudication body in connection with these false charges. That being said, it is submitted that the documentation that has been provided to date does not meet the requisite positivity criteria as established by the World Anti-Doping Agency ("WADA"). Specifically, the following will be established:

1. The carbon isotope results do not satisfy the WADA positivity criteria, in that:
 - a. Only one of four metabolites tested clearly exceeds the 3‰ threshold provided by WADA;
 - b. The measurement value that is the best indicator of exogenous testosterone usage in urine proves that Floyd Landis did not use testosterone; and
 - c. All of the 5 α -Androstanediol ¹³C-values reported by LNDD are inaccurate.
2. Absent a positive CIR result, there is no case to answer under the WADA TECHNICAL DOCUMENT TD2004EAAS.

As such, there is no case to answer, and the proceedings should be dismissed by this Anti-Doping Review Board ("ADRB").

II. SUMMARY OF CARBON ISOTOPE RATIO RESULTS

USADA brings this case primarily based upon the carbon isotope ratio results ("CIR")², which USADA alleges provides evidence of the use of exogenous testosterone. A good summary of the CIR theory is provided at Maitre et al., Urinary Analysis of Four Testosterone Metabolites and Pregandiol by Gas Chromatography-Combustion-Isotope Ratio Mass Spectrometry After Oral Administration of Testosterone, 28 Journal of Analytical Toxicology (Sept. 2004) [attached hereto as Exhibit 1]:

"IRMS allows measurements of slight differences in the carbon isotope ratio (¹³C/¹²C) of the exogenous and endogenous testosterone. Synthetic testosterone is produced from precursors derived from plants with low ¹³C content, whereas the ¹³C and ¹²C content in the natural endogenous form depends on the isotopic carbon composition of the food diet and is influenced by additional effects of human biological processing."

Carbon isotope ratios are expressed in terms of delta units per mil. Maitre went on to describe this calculation as follows:

The symbol δ is the standard notation for expressing carbon isotope ratios. It is defined as parts per thousand deviation of isotopic compositions from that of Pee Dee Belemnite (PDB), and is calculated according to:

$$\delta^{13}\text{C}/\text{‰} = \frac{(^{13}\text{C}/^{12}\text{C})_{\text{sample}} - (^{13}\text{C}/^{12}\text{C})_{\text{standard}}}{(^{13}\text{C}/^{12}\text{C})_{\text{standard}}}$$

Once the $\delta^{13}\text{C}/\text{‰}$ value for the testosterone metabolites is calculated, the positivity criteria mandated by WADA requires that this value be compared between metabolites that are believed to be affected by exogenous testosterone use and those metabolites that are not so affected. See WADA Technical Document TD2004EAAS (attached hereto as Exhibit 2), p.3:

"3. Isotope ratio mass spectrometry:

² This CIR method is also referred to as Isotope Ratio Mass Spectrometry, or "IRMS."

When a parameter of the steroid profile indicates a need to further study, its $^{13}\text{C}/^{12}\text{C}$ value expressed in delta units per mil (‰) or that of its metabolites will be measured and compared to that of urinary reference steroids within the sample not affected by administration. Depending upon the nature of the endogenous steroid suspected to have been administered, the metabolites analysed could be ... androsterone, etiocholanolone, the androstane diols ... while the urinary reference steroid usually analysed by the Laboratories is one of, pregnanediol ... or 11-ketoetiocholanolone.”

Here, the French Lab (LNDD) that analyzed the Landis “A” and “B” samples tested for and calculated the ‰ values for the following testosterone metabolites that are affected by exogenous testosterone administration: androsterone, etiocholanolone, and the androstane diols (5 α -Androstane diol³ and 5 β -Androstane diol⁴). LNDD also tested for and calculated the ‰ values for the following testosterone metabolites that are not affected by exogenous testosterone administration: pregnanediol (specifically, 5 β -pregnanediol⁵) and 11-ketoetiocholanolone⁶. Without conceding the accuracy of the data, LNDD calculated the following values, expressed as corrected and uncorrected values:

For the “A” sample [see Document package, p. USADA 0185]:

| | True Value | Corrected Value |
|------------------|------------|-----------------|
| Androsterone | -27.71 | -25.05 |
| Etiocholanolone | -26.43 | -23.63 |
| 5 α Adiol | -32.12 | -27.72 |
| 5 β Adiol | -28.82 | -23.73 |
| | | |
| 11Ketoetio | -24.10 | -21.06 |

³ Also referred to as 5 α Adiol.

⁴ Also referred to as 5 β Adiol.

⁵ Also referred to as 5 β Pdiol.

⁶ Also referred to as 11-Ketoetio.

| | | |
|-----------------|--------|--------|
| 5 β Pdiol | -26.61 | -21.58 |
|-----------------|--------|--------|

For the "B" sample [see Document package, p. USADA 0351]:

| | True Value | Corrected Value |
|------------------|------------|-----------------|
| Androsterone | -27.93 | -25.29 |
| Etiocholanolone | -26.58 | -23.80 |
| 5 α Adiol | -31.88 | -27.43 |
| 5 β Adiol | -28.79 | -23.69 |
| | | |
| 11Ketoetio | -24.75 | -21.78 |
| 5 β Pdiol | -26.16 | -21.05 |

The final step in the analysis of the positivity criteria is stated in WADA

Technical Document TD2004EAAS (attached hereto as Exhibit 2), p.3, as follows:

"The results will be reported as consistent with the administration of a steroid when the $^{13}\text{C}/^{12}\text{C}$ value measured for the **metabolite(s)** differs significantly i.e. by 3 delta units or more from that of the urinary reference steroid chosen. In some *Samples*, the measure of the $^{13}\text{C}/^{12}\text{C}$ value of the urinary reference steroid(s) may not be possible due to their low concentration. The results of such analysis will be reported as "inconclusive" unless the ratio measured for the metabolite(s) is below -28‰ based on non-derivatized steroid."

In this case, LNDD calculated this difference for all four testosterone metabolites tested. In so doing, LNDD compared the measures of androsterone and etiocholanolone to the urinary reference steroid 11-Ketoetio; and compared the measures of 5 α Adiol and 5 β Adiol to the urinary reference steroid 5 β Pdiol. For reasons that are not stated, LNDD only calculated these measured differences based on corrected values (for sake of

completeness, the measured differences for the true values are provided here as well).

The measured differences are as follows:

For the "A" sample [See Document Package, pp. USADA 0185-0186]⁷:

| | True Measurement | Corrected Measurement |
|------------------------------|------------------|-----------------------|
| Etiocholanolone – 11Ketoetio | -2.33‰ | -2.58‰ |
| Androsterone – 11Ketoetio | -3.61‰ | -3.99‰ |
| 5βAdiol - 5βPdiol | -2.21‰ | -2.15‰ |
| 5αAdiol - 5βPdiol | -5.51‰ | -6.14‰ |

For the "B" sample [See Document Package, pp. USADA 0351-0352]⁸:

| | True Measurement | Corrected Measurement |
|------------------------------|------------------|-----------------------|
| Etiocholanolone – 11Ketoetio | -1.83‰ | -2.02‰ |
| Androsterone – 11Ketoetio | -3.18‰ | -3.51‰ |
| 5βAdiol - 5βPdiol | -2.63‰ | -2.65‰ |
| 5αAdiol - 5βPdiol | -5.72‰ | -6.39 ‰ |

III. THE CARBON ISOTOPE RESULTS DO NOT SATISFY THE WADA POSITIVITY CRITERIA

A. THE WADA POSITIVITY CRITERIA MUST BE READ AS REQUIRING THAT THE ¹³C/¹²C δ VALUE MEASURED FOR ALL METABOLITES

⁷ According to the LNDD documents themselves, these figures have a huge measure of uncertainty of ±0.8‰.

⁸ According to the LNDD documents themselves, these figures have a huge measure of uncertainty of ±0.8‰.

TESTED DIFFERS SIGNIFICANTLY, WHICH CRITERIA IS NOT MET IN THIS CASE

The WADA Positivity criteria, as mentioned above, requires a showing that “¹³C/¹²C value measured for the **metabolite(s)** differs significantly i.e. by 3 delta units or more from that of the urinary reference steroid chosen.” This requirement must be read as requiring that **all metabolites tested** differ significantly as described, i.e. by 3 delta units or more from the urinary reference standard chosen. Such a reading was confirmed in 2006 by the WADA-accredited laboratory in Lausanne:

“According to the technical document of the WADA Laboratory Committee, an athlete would be reported as consistent with the administration of a steroid when the ¹³C/¹²C-value measured for the **metabolites** differs significantly, i.e. by 3.0‰ or more from that of the urinary reference steroid chosen.” Baume et al., Use of Isotope Ratio Mass Spectrometry to Detect Doping with Oral Testosterone Undecanoate: Inter-Individual Variability of ¹³C/¹²C Ratio, Steroids 2006, at p. 6 [attached hereto as Exhibit 3]

In this case, it is clear that the Landis sample does not meet this positivity criteria, as only one of four metabolites tested clearly exceeds the 3‰ example provided by WADA (a second metabolite, measured at -3.51‰ ±0.8‰ on the “B” sample, cannot be said to exceed this threshold). For these reasons, the CIR results do not support a finding of exogenous testosterone use.

Landis submits that this criteria must be read as requiring that **all metabolites** tested exceed this threshold to declare the CIR test as positive. However, at worst, this criteria is vague and ambiguous, as the drafters – WADA – used the incredibly poor and imprecise description “¹³C/¹²C value measured for the **metabolite(s)**.”⁹

It is well settled law that ambiguities in a document or contract must be construed

⁹ Which description was clarified by Baume, supra, as requiring all tested metabolites to be positive under this criteria.

against the drafter of the document. See, e.g., 2 Restatement Contracts, 2d, § 206, p-105 [“In choosing among the reasonable meanings of a promise or agreement or a term thereof, that meaning is generally preferred which operates against the party who supplies the words or from whom a writing otherwise proceeds.”]; United States v. Seckinger, 397 U.S. 203, 216 (1970) [“our interpretation adheres to the principle that, as between two reasonable and practical constructions of an ambiguous contractual provision, such as the two proffered by the Government, the provision should be construed less favorably to that party which selected the contractual language. This principle is appropriately accorded considerable emphasis in this case because of the Government’s vast economic resources and stronger bargaining position in contract negotiations.”]¹⁰; USA Shooting & Q./International Shooting Union (UIT) (CAS 94/129) [““The fight against doping is arduous, and it may require strict rules. But the rule-makers and the rule-appliers must begin by being strict with themselves. Regulations that may affect the careers of dedicated athletes must be predictable ... They should not be the product of an obscure process of accretion.”]; USOC et al. v. IOC et al. (CAS 2004/A/725) [“The rationale for requiring clarity of rules extends beyond enabling athletes in given cases to determine their conduct in such cases by reference to understandable rules. As argued by Appellants at the hearing, clarity and predictability are required so that the entire sport community are informed of the normative system in which they live, work and compete, which requires at the very least that they be able to understand the meaning of rules and the circumstances in which those rules apply.”].

¹⁰ The only basis for the application of the UCI anti-doping regulations, and the WADA Technical Document that WADA and the UCI will assert is incorporated as binding in this case, is the contractual relationship between the parties. The analogy of the Government’s vast economic resources and stronger bargaining power is particularly apt in the context of athletes vs. anti-doping authorities.

Therefore, this positivity criteria must be read to mean that the $^{13}\text{C}/^{12}\text{C}$ δ value measured for the all metabolites tested differ significantly (i.e. by 3 delta units or more from that of the urinary reference steroid chosen). In addition to being required by settled law, such a reading of this positivity criteria makes sense: if an athlete were to take synthetic testosterone, and if that synthetic testosterone would cause a significant difference in the measurement of $^{13}\text{C}/^{12}\text{C}$ for one testosterone metabolite when compared to a urinary reference, then one should expect like or similar changes for all such metabolites tested. Simply stated, synthetic testosterone should not selectively affect these metabolites.

Furthermore, any notion that WADA intended otherwise, or that the WADA-accredited laboratories clearly understood that this positivity criteria would only require a showing of a single metabolite as exceeding the threshold, is easily dismissed by the following published statement by the WADA-accredited laboratory in Lausanne, which statement shortly post-dates the effective date of the WADA Technical Document TD2004EAAS:

“What are the IRMS criteria to determine endogenous T ingestion, that is, does all the measured T metabolite $\delta^{13}\text{C}$ -values or does only one have to be superior to 4‰.” See Maitre, Urinary Analysis of Four Testosterone Metabolites and Pregandiol by Gas Chromatography-Combustion-Isotope Ratio Mass Spectrometry After Oral Administration of Testosterone, 28 Journal of Analytical Toxicology (Sept. 2004) [attached hereto as Exhibit 1].

If even the WADA-accredited laboratories were asking this question, then WADA can hardly claim that its laboratories understood otherwise. Absent a clarification by WADA, which clarification never occurred, this criteria must therefore be read as requiring that all the measured T metabolite $\delta^{13}\text{C}$ -values must show significant differences. Such a

reading is also consistent with the 2006 interpretation of the WADA Technical Document by the WADA-accredited laboratory in Lausanne (See Baume, supra).

In this case, it is clear that the Landis sample does not meet this positivity criteria, as only one of four metabolites tested clearly exceeds the 3‰ example provided by WADA (a second metabolite, measured at $-3.51‰ \pm 0.8‰$ on the "B" sample, cannot be said to exceed this threshold). For these reasons, the CIR results do not support a finding of exogenous testosterone use, and must be considered as negative.

B. THE MEASUREMENT VALUE THAT IS THE BEST INDICATOR OF EXOGENOUS TESTOSTERONE USAGE IN URINE PROVES THAT FLOYD LANDIS DID NOT USE TESTOSTERONE

Additional findings from the CIR results further undermine the erroneous conclusion that those results support a finding of exogenous testosterone use. Published research by WADA-accredited laboratories shows that the measurement 5 β Adiol - 5 β Pdiol is a better indicator of exogenous testosterone usage than other metabolite measurements, and should allow for longer detection periods of exogenous testosterone than the other metabolites.

See Maitre, Urinary Analysis of Four Testosterone Metabolites and Pregandiol by Gas Chromotography-Combustion-Isotope Ratio Mass Spectrometry After Oral Administration of Testosterone, 28 Journal of Analytical Toxicology (Sept. 2004)

[attached hereto as Exhibit 1]:

"This paper describes the time courses of isotopic ratio values in urine of androsterone (Andro), etiocholanolone (Etio), 5 α -androstanediol (5 α A), 5 β -androstanediol (5 β A), and the endogenous reference 5 β -pregnanediol (5 β P) in the frame of an excretion study following oral ingestion of testosterone initially and 13 h later by a healthy, male Caucasian volunteer ...

“Similarly to the T/E ratio, the $\delta^{13}\text{C}$ -values of the four T metabolites decrease rapidly after T administration with a difference of about 5‰ with respect to the endogenous reference 5 β P ...

“our results suggest that measurements of 5 β -androstanediol δ -values allow the detection of a testosterone ingestion over a longer period than other T metabolites $\delta^{13}\text{C}$ -values.”

Therefore, if an athlete used exogenous testosterone, his measured difference 5 β Adiol - 5 β Pdiol should be greater than his measured difference 5 α Adiol - 5 β Pdiol. In the Landis sample, this is not even close to the case: LNDD reported the following corrected values:

For the “A” sample:

5 β Adiol - 5 β Pdiol: -2.15‰
5 α Adiol - 5 β Pdiol: -6.14‰

For the “B” sample:

5 β Adiol - 5 β Pdiol: -2.65‰
5 α Adiol - 5 β Pdiol: -6.39‰

Had Landis used exogenous testosterone, the Maitre publication indicates that his 5 β Adiol - 5 β Pdiol should be at or greater than -6‰, given the measurement of 5 α Adiol - 5 β Pdiol. At a minimum, one would expect the 5 β Adiol - 5 β Pdiol to exceed the threshold of 3‰, which it does not. The only conclusion that can be drawn from the fact that the 5 β Adiol - 5 β Pdiol measurement is well below the threshold, when the WADA-accredited laboratories state that this measurement is the **best indicator** of exogenous testosterone administration, is that Floyd Landis did not use exogenous testosterone.

C. THE 5 α -ANDROSTANEDIOL ^{13}C -VALUES REPORTED BY LNDD ARE INACCURATE

With the 5 α Adiol - 5 β Pdiol measurement being significantly at odds with all of the other measurements in this case, the Review Board must consider the cause of this disparate measurement, which is inconsistent with every other measurement in the CIR portion of the analysis. It is submitted that the explanation for this erroneous measurement can be found in LNDD's calculation of incorrect values for 5 α Adiol, as evidenced by an examination of the negative control urine $\delta^{13}\text{C}$ -values for that metabolite. Simply put, LNDD's $\delta^{13}\text{C}$ -values for 5 α Adiol for the negative control urine show that their equipment was, for some unexplained reason, measuring excessively low $\delta^{13}\text{C}$ -values for 5 α Adiol.

Published data provides guidance for expected $\delta^{13}\text{C}$ -values for 5 α Adiol for negative control urines and for positive control urines. See Aguilera et al., Performance Characteristics of a Carbon isotope Ratio Method for detecting Doping with Testosterone Based on Urine Diols: Controls and Athletes with Elevated Testosterone/Epitestosterone Ratios, 47 Clinical Chemistry 292, 296 Table 3 (2001) [attached hereto as Exhibit 4], showing that mean $\delta^{13}\text{C}$ -values for 73 negative control urines for 5 α Adiol was -26.35‰, with a maximum of -24.55‰ and a minimum of -27.89‰. See also, Maitre, Urinary Analysis of Four Testosterone Metabolites and Pregandiol by Gas Chromatography-Combustion-Isotope Ratio Mass Spectrometry After Oral Administration of Testosterone, *supra*, showing that mean $\delta^{13}\text{C}$ -values for negative control urines for 5 α Adiol was -24.3‰ (± 0.4 ‰). In contrast to those figures, LNDD measured $\delta^{13}\text{C}$ -values for negative control urines for 5 α Adiol in the Landis case of -28.40‰ on the "A" sample (See Document package, p. USADA 0185) and -28.31‰ on the "B" sample testing (See Document package, p. USADA 0351). These figures are inconsistent with reported

figures as shown above, and in fact, are more consistent with measurement or calibration error. See, e.g., Maitre, supra, reporting that mean $\delta^{13}\text{C}$ -values for **positive control urines** for 5 α Adiol was -28.4‰ ($\pm 0.5\%$). See also, Shackleton et al., Confirming Testosterone Administration By Isotope Ratio Mass Spectrometric Analysis Of Urinary Androstenediols, 62 Steroids 379, 383 (1997) [attached hereto as Exhibit 5] ["In our studies with the Chinese subjects, it can be stated that for the five individuals, none had androstenediol $\delta^{13}\text{C}\%$ values less than -28.3 during the control period."]

The LNDD readings for 5 α Adiol in the negative control urine are so low that they must be inaccurate. In fact, those readings look more like positive control urine values than negative controls. If the negative control urine readings for 5 α Adiol are excessively low, it must be the case that the LNDD readings of the Landis sample for 5 α Adiol are also excessively low and inaccurate, thus explaining the large difference in the 5 α Adiol - 5 β Pdiol measurement. As this measurement in the Landis sample is totally at odds with any of the other measurements as discussed above, it is submitted that the result must stem from laboratory error.

D. SUMMARY

As shown above, the WADA Positivity Criteria or CIR analysis of exogenous testosterone usage has not been met:

1. Whereas the WADA Positivity Criteria requires all four testosterone metabolites to provide clear evidence of testosterone usage, 3 of the 4 metabolites must be considered as negative;

2. The only testosterone metabolite that is even arguably positive under the WADA Positivity Criteria is the result of laboratory error and not the result of testosterone usage; and
3. The one metabolite that has been identified by the WADA-accredited laboratories as the best indicator of exogenous testosterone usage, and the longest-term indicator of exogenous testosterone usage, has been reported as negative.

Any one of these deficiencies would alone be sufficient to render the CIR result negative.

IV. ABSENT A POSITIVE CIR RESULT, THERE IS NO CASE TO ANSWER UNDER THE WADA TECHNICAL DOCUMENT TD2004EAAS

A negative CIR result in most cases mandates a dismissal of doping allegations of exogenous testosterone usage. However, in all cases other than a positive CIR Result, WADA Technical Document TD2004EAAS requires that a longitudinal study be performed. No such longitudinal study has been performed in this case, and no such longitudinal data has been provided to the athlete or to this Review Board. For this reason, there is no case to answer, and the case against Floyd Landis must be dismissed.

Doping charges cannot proceed against an athlete based upon an inconclusive/negative CIR test and a single T/E value. Furthermore, the single T/E analysis in this case is replete with fundamental, gross errors. Examples of these errors include:

1. Mismatched sample code numbers that do not belong to Floyd Landis (see, e.g., Document Package p. USADA 0288, alleged confirmation T/E

data on "B" sample, containing different sample number from that assigned to Floyd Landis; see also Document package USADA 0024, LNDD chain of custody documentation regarding receipt of sample, does not identify any sample numbers matching the code number for the Floyd Landis sample). Clinical laboratories making these types of gross errors could easily find themselves answering to a wrongful death lawsuit.

Simply stated, if LNDD cannot get the sample code number correct, how can they be trusted to accurately report quantitative test results?

2. Grossly inconsistent testosterone and epitestosterone samples from sequential tests on the Landis "A" sample:
 - a. See Document Package, pp. USADA 0212 and 0223, testing on Landis sample 995474, vial 10 aliquot (first "A" confirmation analysis), showing testosterone level of 172.23 ng/ml and epitestosterone level of 17.59 ng/ml; and showing corrected values of 127 ng/ml for testosterone and 13 ng/ml for epitestosterone;
 - b. Compare Document package, pp. USADA 0092 and 0101, vial 4 aliquot (second "A" confirmation analysis), showing testosterone level of 61.37 ng/ml and epitestosterone level of 5.20 ng/ml; and showing corrected values of 45.4 ng/ml for testosterone and 3.9 ng/ml for epitestosterone;
 - c. It must be accepted that two test results using the same method on the same urine and tested sequentially should not show three-fold differences in testosterone and epitestosterone. Such differences are

clear evidence of laboratory error, such that none of these results can be accepted as accurate.

“Where doubt has been created with regard to the test procedure, such doubt must go to the benefit of the athlete.” USA Triathlon v. S. Smith (CAS 99/A/241). The LNDD laboratory documents are replete with such gross errors and ineptitude that their results in this case cannot be seriously accepted as accurate. At a minimum, those laboratory errors must go to the benefit of the athlete, and must result in a finding that the T/E results are wholly unreliable.

V. CONCLUSION

For the foregoing reasons, it is submitted that there can be no case to answer, and that the charges against Floyd Landis must be immediately dismissed.

RESPECTFULLY SUBMITTED,

Re: RE: UCI File No. 29/06
Tour de France, July 20, 2006
Sample #995474

Dear Terry,

The following members of the United States Anti-Doping Agency's Anti-Doping Review Board Panel met by teleconference on September 18, 2006, to review the above referenced matter.

This Panel considered the written information submitted to it and concluded that there was sufficient evidence of doping to proceed with the adjudication process as set forth in USADA's Protocol for Olympic Movement Testing.

GC/C/IRMS and GC/MS in "Natural" Steroids Testing

Centre de recherche en santé humaine, INRS-Institut Armand-Frappier, Montréal

Introduction

Testing for the administration of natural steroids is a complex task requiring the identification and quantification of a number of parameters of the steroid profiles, one of which being the T/E¹ value. Complementary diagnostic information is gained from the determination of the urinary concentration of testosterone, epitestosterone, androsterone and etiocholanolone. By 1997, three different groups had proposed the GC/C/IRMS as a promising tool for the detection of the administration of testosterone (Aguilera et al., 1996; Becchi et al., 1994; Horning et al., 1997; Shackleton et al., 1997) and since then, others have described the values of the ¹³C/¹²C (δ ¹³C₁₀₀) of urinary androgens within the athletic populations and following the administration of DHT, epitestosterone or testosterone precursors such as DHEA.

In this paper, we present the results afforded by the analysis of urine samples collected following the administration of testosterone, androstenedione and DHEA as well as examples of the combined GC/MS and GC/C/IRMS individual "profiles" which have been proven to be useful in the investigation of putative doping cases, to discriminate inter alia, between the administration of a source of testosterone and 19-nortestosterone from a natural and systematic excretion of elevate T/E values or an increased endogenous norandrosterone production.

Experimental

"Androstenedione complex", DHEA and Nordione were purchased with an authorization from Health Canada (8572.090.98) from Price's Power International (International Nutrition and

¹ The T/E value is the corrected area ratio of both peaks.

Export, Newport News, Virginia 23608, USA). One capsule was administered to volunteers after verification of its content by GC/MS analysis. Urine samples were collected 24 hours before and up to one week after the administration and were prepared and analysed according to anabolic agents' procedure for the GC/MS steroid profiling. The preparation of the specimens for the GC/CIRMS was carried out according to a modification of the method proposed by Shackleton (1997) for the analysis of testosterone and precursors. The underivatized extracts of hydrolysed steroids (Ayotte et al., 1996) were analysed as such when the concentration of nortestosterone was greater than 30 ng/mL or following an HPLC fractionation for lower levels. The identity of the peaks was verified by GC/MS. Authentic standards were purchased from Steraloids Inc. (Wilton, NH 03086).

Results and discussion

Testosterone, androstenedione and DHEA:

The administration of testosterone and precursors, androstenedione and DHEA can be detected by the GC/MS determination of parameters of the urinary steroid profile that are abnormal when compared to the ranges of values normally found in human (Donike et al., 1983, 1993). The oral intake of androstenedione and DHEA was shown to transiently increase the excreted T/E value in females and, although not systematically, in some males (Bowers, 1999; Bory et al., 1998; Van Banno et al., 1998; Gault and Palonek, 1998; Uralis and Gillette, 1999; Lévésque and Ayotte, 1999; Lévésque et al., 1999). Other alterations of the urinary steroid profile, such as an abnormally high concentration of androstene and etiocholanolone, the presence of the characteristic hydroxylated metabolites glucuro- and sulfoconjugated, 6 α -hydroxyandrostenedione, 6 β -hydroxyandrostenedione for androstenedione and for DHEA, the increased excretion of 7 β -hydroxyandrostenedione with suppression of 16 α -hydroxyandrostenedione, served as basis for reporting positive findings (Lévésque and Ayotte, 1999; Lévésque et al., 1999). The disruption of the normal urinary profiles of androgens metabolites can be demonstrated by comparison with the described population reference ranges that are summarised in table 1 (Ayotte, 1997 and reference cited therein; Lévésque and Ayotte, 1999; Catlin et al., 1997; Geyer et al., 1997; Bauminger and Bowers, 1994). It also requires the

investigation of the athlete's previous or subsequent tests results in order to exclude the few individuals who naturally produce urine samples in which elevated T/E values are systematically measured. A systematic excretion of elevate T/E values reflects a normal condition, while sudden increase deviating from the athlete's norm, is consequent with the administration of source of testosterone, including the precursors (Ayotte, 1997; Geyer et al., 1997). The evaluation of some cases that we have made in the past years, based upon the variation of the individual's T/E values, are illustrated in Table 2.

Table 1: Description of the steroid profiles in the athletes' reference populations

| Parameter | Description (97.5%) | | Reference |
|--------------|---|--|---|
| | Male athletes | Female athletes | |
| T/E values | 4.2 (n=11000) 5.2 (n=5000) 6.5-7.0 (99%; n=22806) | 3.2 (n=4667) 6.3 (n=1700) | Lévésque and Ayotte, 1999 Geyer et al., 1997 Bauminger and Bowers, 1994 |
| T (ng/mL) | 5.6 (99%; n=3700) 106 ng/mL (n=9500) | 26.4 ng/mL (n=3740) 57 ng/mL (n=1700) | Catlin et al., 1997 Lévésque and Ayotte, 1999 |
| A (ng/mL) | 137 ng/mL (n=5000) 6703 ng/mL (n=9500) | 5170 ng/mL (n=4200) 6439 ng/mL (n=1700) | Geyer et al., 1997 Lévésque and Ayotte, 1999 |
| Etio (ng/mL) | 6689 ng/mL (n=5000) 5294 ng/mL (n=9500) | 4938 ng/mL (n=4200) 6107 ng/mL (n=1700) | Geyer et al., 1997 Lévésque and Ayotte, 1999 |

Table 2: Evaluation of elevate T/E values in athletes' samples

| Normally elevated cases | | T/E value | Remarks |
|-------------------------|-----------|-----------|------------------------------------|
| Mean | Variation | Range | |
| Male 1 | 4.8 | 23% | 2.9 to 6.9 (n=20) |
| Male 2 | 1.3 | 13% | 1.0 to 1.5 (n=11) |
| Male 3 | 5.8 | 25% | 3.1 to 8.7 (n=14) |
| Female 1 | 0.8 | 38% | 0.3 to 1.2 (n=16) |
| Female 2 | 1.1 | 43% | 0.5 to 2.1 (n=13) |
| Female 3 | 6.1 | 39% | 3.0 to 9.2 (n=11) |
| Positive cases | | | |
| Male 4 | 3.9 | 68% | 2.3 to 10.6 (n=8) |
| | 2.9 | 24% | 2.2 to 3.2 (n=7) |
| Male 5 | 1.8 | 70% | 0.9 to 7.3 (n=21) |
| | 1.5 | 22% | 0.9 to 2.2 (n=20) |
| Female 4 | 2.0 | 132% | 0.6 to 11.6 (n=16) |
| | 1.2 | 38% | 0.6 to 1.9 (n=14) |
| | | | Excluding two elevate test results |

Several groups have reported significantly changed carbon isotopic $^{13}\text{C}/^{12}\text{C}$ values (expressed as $\delta^{13}\text{C}/\text{‰}$) in the androgens metabolites excreted following the administration of testosterone (Aguilera et al., 1999, 2000, 2001), DHT, epitestosterone, DHEA (Shackleton et al., 1997, Ueki and Okano, 1999), and corticosteroids (Bourgonne et al., 2000). The methods described are based upon the comparison of the $\delta^{13}\text{C}/\text{‰}$ values of the urinary androgens metabolites to reference endogenous steroids, and products from earlier processes of the endogenous biosynthetic pathways. The urinary androgens metabolites most frequently analysed are androstosterone, etiocholanolone, 5 α - and 5 β -androstane-3 α ,17 β -diol, whereas the endogenous unaltered reference steroids are pregnanediol, pregnanetriol and cholesterol. The analysis of $\delta^{13}\text{C}/\text{‰}$ natural values amongst athletes did not indicate differences related to the nationality but to the diet (Aguilera et al., 1999, 2000, 2001; Shackleton et al., 1997, Ueki and Okano, 1999). To compensate for the different analytical methodologies and to allow for inter-laboratory comparison, it was proposed to use the ratio of the values of the androgens metabolites to those of the endogenous reference steroids in each sample (Shackleton et al., 1997).

19-nortestosterone and precursors, norandrostenedione and norandrostenediol:

The administration of 19-nortestosterone and of its precursors, 19-norandrostenedione and 19-norandrostenediol, results mainly in the excretion of 19-norandrostosterone (NA) and 19-noretiocholanolone (NE), mostly found in the glucuronidated form. The period during which the metabolites can be detected, is drastically reduced when the oral preparations are taken and the relative amounts of NA and NE can vary based upon the individual and the product taken (Engel et al., 1958; Massé et al., 1985; Schinzel, 1996; Kintz et al., 1999). The low excretion of endogenous norandrostosterone is normally not detected in human urine samples during routine doping control testing, with limits of detection of around 0.2 to 0.5 ng/mL, excepting specimens collected during pregnancy (Reznik et al., 1987). A more sensitive analytical technique such as the GC/HRMS, a larger volume of urine extracted and an extensive sample clean-up are needed to detect, identify and quantify endogenous NA, which in some male specimens was quantified at levels varying around 0.01 to 0.32 or 0.05 to 0.6 ng/mL, well below the limit of the IOC (Jennaneau et al., 1999; Le Bizac et al., 1999; Delemmin, 1999). In females, the level of NA is normally also very low, reaching a mean maximum value of 0.6 ng/mL during the ovulation

(Hennrichbach et al., 2000). The statistics collated by the IOC indicate that each year, are 0.24% of the A-samples analysed were reported to contain norandrostosterone, making norandrostosterone one of the anabolic agents most frequently found in athletes' samples along testosterone.

Natural Steroids $\delta^{13}\text{C}/\text{‰}$ values

We have measured the $\delta^{13}\text{C}/\text{‰}$ values of urinary steroids excreted in mixed athletes' same different nationalities and found them to be similar to those reported by others (table 3).

Table 3: Reference $\delta^{13}\text{C}/\text{‰}$ values measured in athletes' samples

| Steroid | n | Mean | Std dev. | $\delta^{13}\text{C}/\text{‰}$ | Range |
|-----------------|----|-------|----------|--------------------------------|----------|
| Androstosterone | 78 | -23.4 | | 1.6 | -19.9 to |
| Etiocholanolone | 78 | -23.3 | | 1.3 | -20.0 to |
| Pregnanediol | 56 | -24.9 | | 1.2 | -22.1 to |
| Pregnanetriol | 68 | -23.8 | | 1.5 | -20.8 to |
| Cholesterol | 68 | -24.2 | | 1.5 | -21.1 to |

Synthetic $\delta^{13}\text{C}/\text{‰}$ values

The GC/HRMS analysis of samples collected before and following the administration of testosterone and of a single oral dose of androstenedione and DHEA have shown that the content of the androgens metabolites differed significantly from their original value (stable the course of the study) and from those of the reference steroids, going to the depleted value measured in synthetic steroids. Examples of results are summarised in tables 4, 5 and in 6, 1, 2.

We are now using the combination of GC/MS and GC/HRMS to evaluate "testosterone" Examples of normally and abnormally elevated T/E excretion are presented in table 6.

19-nortestosteroids

Twenty-five urine samples, analysed between 1992 to 1999, containing nortestosterone in amounts ranging from 35 to 11000 ng/mL, were re-analysed by GC/CIRMS and so were the urine samples collected after the administration of nortestosterone (commercial Nortestone). The $\delta^{13}\text{C}_{16}$ values measured in the excreted nortestosterone and nortestosterone were both significantly different than those of the reference steroids and of androstosterone and etiocholanolone, excepting of course, athletes' samples in which elevated T/E values were also measured.

Endogenous nortestosterone (around 2 ng/mL), excreted during the 12th and 14th weeks of pregnancy of two different persons, was analysed by GC/CIRMS following its isolation from a large volume of urine. The $\delta^{13}\text{C}_{16}$ values then measured were found to be similar to the other endogenous steroids, androstosterone, etiocholanolone, pregnanediol and pregnanetriol. The results are summarised in table 7.

Table 7: $\delta^{13}\text{C}_{16}$ values of nortestosterone in 1) nortestosterone positive samples 2) nortestosterone samples 3) pregnancy samples

| Pregnancy 12 th week ³ | -23,6 | | -24,9 | -23,1 | | 1,02 |
| Pregnancy 14 th week | -23,0 | | -26,1 | -23,0 | | 1,00 |

Conclusion

The combination of GC/MS and GC/CIRMS has been proven useful to the evaluation of cases where the administration of "natural" steroids was suspected. The population reference range of the diagnostic parameters of both techniques are now well described. The ratio of the $\delta^{13}\text{C}_{16}$ values measured in the steroids metabolites to the unaltered reference steroids is the only way to compensate for the many diets and for the different methods that are currently used in the laboratories. Alone, absolute values associated with either synthetic or natural steroids cannot form basis of the decision, significant differences having reported for the reference population. The ratio of 1,1:1,0 proposed by Shackleton (1997) for testosterone seems also adequate for other steroids. The choice of the reference steroids must be made taking into account the alterations of the values that could be produced following the administration of precursors such as pregnenolone. When the concentration and the volume of specimen available permitted the injection of more than 20 ng, the ratios of the urinary synthetic nortestosterone to the unaltered reference steroids were always high since the contribution of natural nortestosterone can be virtually excluded. Natural values, similar to those of the reference steroids, were obtained during pregnancy.

Chapter 35

Effects of Testosterone and Related Androgens on Athletic Performance in Men

KARL E. FRIEDL

In spite of quantitative differences in the gene products of tissues from males and females, there are few important sexual differences in the genome, with the exception of the male-specific Y chromosome. The major function of this chromosome is to determine sexual differentiation; in its absence, ovaries develop. It is, then, the secretory products of the gonads that are responsible for sexual dimorphism. . . . As a consequence of its widespread action, testosterone is the major hormone responsible for the sexual dimorphism of nonreproductive tissues.

Bardin & Catterall 1981, p. 1285

Introduction

Although gender differences in body size and upper body strength may have been evident for centuries, the basis of these differences is still poorly understood. This ignorance hampers our ability to predict the effects of supplemental androgens administered to normal adult males for performance enhancement. Androgens administered to androgen-deficient men, prepubertal boys and normal women can produce marked effects on size and strength (Stanhope *et al.* 1988; Bhasin *et al.* 1997; Elbers *et al.* 1999), but it does not necessarily follow that an excess of androgens to normal men will provide more of the same effects along the same continuum. There is no specific disease of androgen excess in males, perhaps suggesting that more androgen does indeed produce more of the same biological effects (Can a man *be* over-virilized?) (Bardin *et al.* 1990). Alternatively, it could be reasonably expected

that limiting mechanisms simply will not allow open-ended or cumulative effects to occur (e.g. changes in receptor density and binding activity, negative feedback loops and non-linear interactions with other hormones) (Glass & Vigersky 1980). In this case, observed effects from supraphysiological doses of androgens may contrast those that occur in nature, producing pharmacological effects that are very different than those associated with male characteristics (e.g. stroke risk, gynecomastia, osmoregulatory changes). For practical purposes, supraphysiological could be defined as a dose that increases circulating levels of testosterone above the normal range, or other androgen formulations with rough bioequivalence to these above-normal testosterone levels (even though measured testosterone may be markedly suppressed); in some regards, any administration of exogenous androgen is supraphysiological because it does not precisely mimic circadian fluctuations and other properties of the body's own hormonal secretions. In the absence of data, speculative and anecdotal self-experiments by athletes have led to widespread gym lore about androgen use, and non-users are left with concerns about unfair performance advantages. A greater understanding of androgen physiology can improve the scientific basis of training regimens for athletes and help define the full range of modifiable human performance. This chapter considers the available data on testosterone and related androgenic steroid effects on athletic performance and attempts to expand on earlier thoughtful reviews (Wright 1980; Haupt & Rovere 1984; Wilson 1988; Yesalis 2000).

Metabolism and action of testosterone and related androgenic steroids

The basic physiology of testosterone production and secretion is relatively well known, while the far-reaching effects of testosterone on cells throughout the body, as well as interactions with other anabolic hormones, are not as well understood (Bardin & Catterall 1981). Testosterone is a steroid hormone that is made from cholesterol through a series of enzyme-regulated steps in the Leydig cells of the testes of men, and in the adrenal cortex of men and women. The key regulator of the testicular secretion is luteinizing hormone (LH), a protein hormone from the pituitary gland. LH secretion, in turn, is regulated by gonadotropin-releasing hormone (GnRH), which is regulated in the hypothalamus. LH and GnRH secretion are controlled, in part, by circulating levels of testosterone in a negative feedback loop. If testosterone or a related androgenic compound is administered artificially, the system down-regulates, reducing the amount of testosterone synthesized by the testes. If higher than normal circulating levels are sustained by administration of androgen, the testes substantially reduce testosterone and sperm production, reducing the volume of the testes as the seminiferous tubules are depopulated of maturing germ cells (a readily reversible phenomenon). This noticeable reduction in testicular volume (Kiraly 1988; Friedl *et al.* 1991) is one of the androgen effects that make blinded studies in androgen-experienced athletes difficult to conduct.

Testosterone's effects on body tissues are far more complicated than its production and secretion. Testosterone is directly active in most tissues, acting through a specific androgen receptor. Additionally, in some tissues such as the prostate and hair follicles, testosterone is converted to 5 α -dihydrotestosterone (DHT). DHT has greater potency than testosterone on androgen receptors, but is also more rapidly metabolized to biologically inactive 5 α -androstane diols. In fat cells, where high concentrations of aromatase enzyme are present, some of the testosterone is converted to estrogen, with estrogen actually playing important roles in the mediation of apparent testosterone actions in some tissues such

as intra-abdominal fat metabolism, regulation of key hepatic proteins, bone mineral metabolism and some brain effects (e.g. regulation of gonadotropin secretion). In muscle cells, testosterone appears to act directly on androgen receptors, which are present in much lower density than in more androgen-responsive tissues such as prostate, and then is excreted as a water-soluble conjugate, 3 α -androstane diol glucuronide; muscle lacks the 5 α -reductase to convert testosterone to DHT (Michel & Baulieu 1980; Hughes & Krieg 1988). Androgens, including testosterone and DHT, are bound to a variety of carrier proteins in circulation, most specifically to sex hormone binding globulin (SHBG), but also non-specifically to albumin. This constitutes a large circulating 'reserve' pool of immediately available steroids that has some protection against metabolism and excretion while bound, acting in a kinetic balance with receptors and competitive ligands that may vary between tissues, with only 1–2% unbound (or 'free') at any time. Testosterone activates the secretion of other potent anabolic hormones such as insulin-like growth factor I (IGF-I) and erythropoietin, and potential benefits to athletic performance may accrue from these indirect effects of androgen. Localized effects of testosterone, including such interactions at the tissue levels, may be very important and are just beginning to be appreciated with the availability of modern research methods such as transgenic animal studies. Testosterone can also bind to other receptors such as glucocorticoids, in this case providing competitive inhibition of certain catabolic stress responses induced by cortisol; thus, part of the anabolic action of testosterone may actually be exerted through this crossover binding to modify catabolic responses (Hickson *et al.* 1984; Janne 1990).

Pharmacological compounds that have been developed to extend or modify the effect of testosterone build on some of these understood effects of androgens (Liddle & Burke 1960; Kruskemper 1968; Kochakian 1988). Thus, steroids that cannot be converted to estrogenic compounds or to DHT will exhibit characteristic effects different from those of testosterone, with reduced effects on bone or prostate, respectively (Sundaram *et al.* 1995). Some steroid-using athletes include aromatase inhibitors

in the drug regimen to block conversion to estrogens, or use estrogen receptor blockers to prevent estrogenic actions, in attempts to prevent gynecomastia and other side effects (Friedl & Yesalis 1989). Most androgenic-anabolic steroids have been developed to reduce the 'androgenic' effects on reproductive tissues such as prostate, in favor of 'anabolic' effects on muscle and bone; these would focus on steroid structures that cannot be readily reduced to DHT (Hershberger *et al.* 1953). Testosterone administered either orally or by injection promptly reaches circulation and is rapidly removed by the liver and metabolized to products that can be readily excreted in urine or bile. Modifications with 17-alkylation protect testosterone against this rapid elimination, making methyl testosterone an orally active androgen, but the metabolites produced in various tissues are 17-alkylated compounds that will exhibit different binding properties and biological effects. Adverse effects on the liver are one of the properties inherent in the orally active 17-alkylated androgens. Methandienone (Dianabol) is the most important orally active 17-alkylated androgen in the studies of athletic performance (Friedl 2000). This was the orally active drug of choice by steroid-using athletes in the 1960s and 1970s but has been since taken off the market by major drug manufacturers (Yesalis *et al.* 1988). Modifications of testosterone with an ester side chain also protects against rapid elimination, but because this side chain can be hydrolyzed to provide graded release of testosterone into circulation from deep intramuscular injection sites, the effects are different than those of the 17-alkylated compounds. The duration of action of these esterified androgens is roughly dependent on the length of the side chain; a relatively short side chain in testosterone undecanoate makes this a relatively short acting testosterone (usually used orally) (Schurmeyer *et al.* 1983), while high levels of testosterone can be maintained with testosterone enanthate (TE) or testosterone cypionate in weekly injections, and the very long chained testosterone buciclate maintains circulating levels for months (Behre & Nieschlag 1992). A compound that differs from testosterone only by the elimination of one methyl group at the 19 carbon position ('19-nortestosterone' or nandrolone) was

developed to try to reduce androgenic side effects on prostate through its properties that prevent aromatization to estrogens and its metabolism to compounds that are weaker than DHT (e.g. 19-nordihydrotestosterone) (Hershberger *et al.* 1953; Sundaram *et al.* 1995). Nandrolone esters (e.g. nandrolone decanoate or 'Deca-Durabolin') and testosterone esters (e.g. TE) are the most commonly used androgenic preparations today, and these are the compounds that have been used in the majority of modern studies on performance effects. A wide variety of androgens are active in muscle, while requiring greater selectivity for some other tissues; for example, protection of bone against glucocorticoid effects requires an aromatizable androgen, while nandrolone compounds are effective in preserving muscle but not bone (Crawford *et al.* 2003). Any administration of exogenous steroid is non-physiological, even at doses that restore mean circulating levels to 'normal', as there is a large fluctuation in normal circulating levels of testosterone during the day.

Dietary supplements that are legally marketed as 'steroid replacers' in the USA include a wide range of products (e.g. sterols, sapogenins, androgen metabolites, yohimbe bark, boron), none of which have any convincing scientific basis for performance enhancement in normal men. Some products have been tainted with banned substances that will give a positive drug test; others are simply bogus and even harmful (Friedl *et al.* 1992b). There is no over-the-counter drug that comes close to the actions of testosterone, or significantly stimulates its production or release in the body (King *et al.* 1999). If such an effective product surfaced, it would likely be added to the list of androgens and other substances banned by athletic federations.

Most recently, new 'designer' steroids have been detected in urinalyses from elite athletes (Catlin *et al.* 2002). Tetrahydrogestrinone is a compound related to gestrinone, a steroid used to treat endometriosis in women, and is the latest to turn up in drug testing in a wide variety of sports including track and field, football and boxing (Knight 2003). The novelty is not in some new marvelous mechanism of action, but rather in the fact that the compound was new to human use and therefore not

specifically tested for in routine drug screens. Other synthetic steroids have been administered in attempts to correct the abnormal profile of androgen metabolites that signal exogenous use of androgens (Aguilera *et al.* 2002). The use of new drugs with little or no evaluation of human safety should be of great concern to normal healthy athletes.

For purposes of this chapter, anabolic steroids are used to denote synthetic androgenic steroids other than the testosterone compounds, but are used somewhat interchangeably, as anabolic and androgenic properties are notional and have never been effectively separated (Kochakian 1988).

Is there a male athlete hypogonadal equivalent to athletic amenorrhea?

Environmental regulators of testosterone secretion

Female athletes have been commonly warned that reproductive cycles may cease with too much exercise, as part of a 'syndrome' involving exercise, amenorrhea and bone mineral loss. Extrapolations from the theory of an athletic amenorrhea in men suggest that with high volume physical training, testosterone will be suppressed in male athletes. Furthermore, it has been suggested that these athletes might benefit from 'replacement' androgen therapy. This interpretation may have started with military training studies in which marked reductions in testosterone were noted in healthy young men (Aakvaag *et al.* 1978). In normal men working hard with inadequate energy intake, testosterone can fall nearly to castrate levels. This has been shown in high school wrestlers during their wrestling season while they are energy-restricted (Strauss *et al.* 1985; Roemmich & Sinning 1997) and in elite soldiers during short- and long-term intensive training (Opstad 1992a; Friedl *et al.* 2000). Guezennec *et al.* (1994) demonstrated a testosterone decline with increasing energy deficit in French commandos. However, testosterone levels are rapidly restored to normal with refeeding, even in the face of other persistent stressors such as workloads exceeding 25 MJ·day⁻¹ (6000 kcal·day⁻¹) (Friedl *et al.* 2001). Thus, these large reductions, generally much

larger than those observed in athletes in training, can be explained by inadequate energy intake and not as an exercise-specific effect (Friedl 1997). As it turns out, even the concept of a female athletic amenorrhea produced by high volume exercise may not be correct; earlier studies were confounded by under-reporting food intake. As observed in men, energy deficit, not exercise, appears to be the key stressor affecting reproductive cycles in women (Loucks & Thuma 2003; Loucks 2004).

Psychological factors also affect testosterone levels in healthy men. The thrill of victory may produce short-term increases in circulating testosterone levels (Ursine *et al.* 1978; Elias 1981), while anxiety produces reliable declines (Bourne *et al.* 1968; Kreuz *et al.* 1972; Francis 1981). Mood and motivation in human research is difficult to control or ethically manipulate. However, in one novel study of men in parachute training making a stressful jump out of a high tower, the initial jumps resulted in a marked stress effect with acute suppression of testosterone and elevation of cortisol ('distress'), while later experienced jumps led to acute elevation of testosterone and no change in cortisol ('eustress') (Ursine *et al.* 1978). There is a large body of literature on the effects of defeat and chronic stress on testosterone suppression in animals that suggests this is a key regulator of normal testosterone in mammalian species (Blanchard *et al.* 1993). In humans, chronic anxiety appears to have a prominent suppressive effect on testosterone and may even provide a more reliable indicator of a noxious stress than traditional measures of the hypothalamic-pituitary-adrenal axis such as cortisol (Kreuz *et al.* 1972; Francis 1981; Hellhammer *et al.* 1985).

Effects of resistance and endurance exercise on testosterone

Exercise itself does not appear to be an important regulator of testosterone secretion through either primary (actions at the testes) or higher levels (actions at the pituitary or hypothalamus), although little is known about the neurobiology of exercise (Rogol *et al.* 1984), or any direct signals from exercising muscle that may affect the gonadal axis. Endurance athletes have been variously reported

Fig. 35.1 Apparent relationship between duration of exercise and serum testosterone from various studies, suggesting a role for a progressive metabolic stimulus such as declining glucose availability on regulation of testosterone secretion. (From Viru 1985.)

to have modest reductions in resting testosterone levels (Wheeler *et al.* 1984; De Souza *et al.* 1994), or no differences (Bagatell & Bremner 1990; Lucia *et al.* 1996), compared to sedentary controls. Male runners reducing their weekly mileage from 81 km·wk⁻¹ to 24 km·wk⁻¹ demonstrated no change in low, normal testosterone levels, even though creatine kinase levels were reduced by half, reflecting a reduction in muscular strain (Houmard *et al.* 1994). The biological significance of this altered status to low-normal circulating levels observed in some studies is unknown.

Exercise can acutely increase or decrease circulating testosterone, depending on the mode and intensity of exercise (Schmid *et al.* 1982; Viru 1985). Increases occur during and after relatively short, high intensity work such as resistance training or sprint events, while declines are associated with increasing duration endurance events and are especially noted in marathon and ultra-running events. Endurance exercise has been reported to decrease testosterone by as much as half, even after appropriate comparison to same time-of-day baseline values (Dessypris *et al.* 1976; Morville *et al.* 1979; Kuoppasalmi *et al.* 1980; Schurmeyer *et al.* 1984). These effects observed during or shortly after the exercise period, may persist into the next day or two after cessation of exercise. The physiological consequences of this short-term suppression are uncertain; this decline is comparable to the changes observed daily in normal men, and the observed reductions still do not fall into the range of a clinical

hypogonadism that would normally justify treatment. Mechanisms for this change with prolonged exercise have been variously postulated and investigated. Catecholamine effects on testicular blood flow (Collu *et al.* 1984) and cortisol suppression of testosterone production (Bambino & Hsueh 1981) do not seem to occur at physiological levels (Sapolsky 1985, 1986). Increased clearance rates of testosterone by exercising muscle (e.g. increased excretion of 3 α -androstenedione-glucuronide) appears to occur (Ponjee *et al.* 1994), but could be construed as an increased biological action reflected in greater turnover at the muscle target site, rather than a deficiency state. It may be that this transient decline in testosterone that appears to increase with duration of exercise (Fig. 35.1) is explained simply by a within-exercise energy deficit, highlighting the sensitivity of GnRH to low glucose levels in the hypothalamus (Opstad 1992b; Loucks 2004). A similar effect of a progressive 'starvation' profile has been suggested for changes in thyroid hormone levels during prolonged exercise (O'Connell *et al.* 1979). Some extreme endurance athletes recognize the need for liquid carbohydrate replenishment during their exercise (Saris *et al.* 1989), although whether or not this better sustains testosterone levels and muscle mass has not been studied.

In contrast to prolonged endurance exercise, resistance and sprint exercise usually produces short-term elevation in testosterone concentration (Sutton *et al.* 1973; Cumming *et al.* 1986; Kraemer *et al.* 1991), or no change observed (Guezennec *et al.*

1986). Several mechanisms would be reasonably expected to temporarily increase serum concentrations. Liver blood flow markedly declines with increasing intensity of exercise (Rowell *et al.* 1964) and would reduce hepatic clearance and temporarily increase serum concentrations. Fluid shifts with movement out of the vascular space during exercise (Wilkerson *et al.* 1980) would increase the concentration of all protein-bound hormones such as testosterone, which cannot move with the fluid. Dopamine and prolactin may regulate testosterone release, but in one study, testosterone changes were unaffected when the exercise-induced rise in prolactin was blocked by L-dopa (Jezova-Repceckova *et al.* 1982). Sympathetic activity may also play a role in exercise-induced testosterone increase (Jezova & Vigas 1981).

Effects of endogenous testosterone changes on performance

Temporary exercise-induced declines in testosterone may not have much effect on body composition, as much more profound reductions in testosterone lasting weeks have relatively small effects. Artificial hypogonadism induced for 10 weeks in healthy young men who were not exercising produced a 2 kg shift in lean-to-fat tissue balance (Mauras *et al.* 1998). In healthy young soldiers who were underfed while working hard, individual differences in the level of testosterone suppression was a relatively small contributory factor in the proportion of lean tissue lost during weight loss over 8 weeks, even though the association was statistically significant (Friedl 1997). This is supported by findings in animal studies, where fasting and exercise caused smaller testosterone reductions in endurance-trained animals and this difference was also associated with higher lipolysis and decreased glycogenolysis, possibly protecting muscle protein (Guezennec *et al.* 1984b).

Acute increases in testosterone observed with resistance exercise may be enough to trigger tissue receptor-level changes or other anabolic hormones, but this remains unknown. In training studies conducted by Kraemer *et al.* (1991), a comparison of bodybuilder to power lifter routines with differ-

ences in repetitions and duration of rest periods between sets demonstrated large differences in growth hormone responses, but a minimal difference in the magnitude of testosterone increases in either routine. One can only speculate on the significance of brief testosterone changes in either direction to synergistic actions with other musculotrophic hormones such as local tissue activity of IGF-I, including in the final determination of muscle hypertrophy under the influence of strength demands for strength athletes and the slimming down of muscle mass that would be advantageous for distance runners.

Effects on muscle mass: how big can humans get?

Increases in total body weight

Androgen supplementation to normal men increases body weight and amino acid incorporation into muscle protein. The precise nature of the observed weight gain, how much can be added with continuous androgen administration, and how much will remain after steroid cessation is far from clear. In general, humans increase or lose lean and fat mass in roughly the same proportions as they move up and down the scale of energy balance, with approximately two-thirds of the changes in fat mass. Forbes has plotted these trends on the basis of data from overfeeding and underfeeding studies (Fig. 35.2) (Forbes 1993). He suggests that supplementation with anabolic hormones moves individuals off the normal trajectory, with a substantial increase in the lean component and even a reduction in the fat component. In other words, androgen supplementation has been suggested to provide a nutrient partitioning effect similar to the class of β -adrenergic agonist drugs that have been developed for animal food production (e.g. clenbuterol) that favor a specific increase in the lean mass component. Forbes was one of the first to illustrate this principle in a study with high-dose androgen administration to normal men (see Fig. 35.3, below) (Forbes *et al.* 1992). However, all studies to-date, including this one, leave nagging questions about the role of dietary intakes, training effects, and the

Fig. 35.2 Conceptual relationship between fat and lean components during changes in body weight and the effect of superimposed anabolic hormone administration. GH, growth hormone. (From Forbes 1993.)

validity of the assumptions underlying each of the methods used to estimate these changes.

Weight gain is a well-known side effect of androgens used in clinical practice and in male contraception trials using supraphysiological doses of injectable testosterone esters (typically 200 mg·wk⁻¹) (World Health Organization Task Force 1990; Young *et al.* 1993). A typical period of 6 weeks or longer of continuous testosterone ester administration to normal adult males provides about 3–5 kg of weight gain within the first few weeks (Mauss *et al.* 1975; Friedl *et al.* 1990, 1991; Welle *et al.* 1992; Young *et al.* 1993; Pope *et al.* 2000). Orally active androgens have the same effects. A large series of studies in the early 1970s with methandione (Dianabol) showed consistent increases of about 2 kg in men given at least 10 mg·day⁻¹ for 3–4 week periods, regardless of physical training status (Friedl 2000). It is not clear that this weight gain effect is either dose- or time-dependent. In the male contraceptive studies that have given androgen (testosterone enanthate, TE) at a dose of 200 mg·wk⁻¹ for more than a year, the individuals do not continue to gain weight, despite the sustained doubling or tripling of circulating testosterone levels with this

dosing regimen. There were no effects in normal men at typical doses used in replacement therapy for hypogonadal men (e.g. 100 mg·wk⁻¹ of testosterone cypionate or nandrolone decanoate, ND) (Crist *et al.* 1983), but doubling the dose (ND, 200 mg·wk⁻¹ for 8 weeks) produced significant increases in weight (Hartgens *et al.* 2001). In another study, androgen doses that produce 'replacement' levels in normal men (TE, 100 mg·wk⁻¹) did not change body weight, while high levels of TE (300 mg·wk⁻¹) and two doses of ND (100 mg·wk⁻¹ and 300 mg·wk⁻¹) produced significant weight gain (Friedl *et al.* 1991). A study that was twice as long with comparable weekly dosing (TE 280 mg·wk⁻¹) did not cause twice as much weight gain (Friedl *et al.* 1990). Bhasin *et al.* (1996) doubled the weekly dose of testosterone (TE, 600 mg·wk⁻¹ for 10 weeks) and also observed a similar final increase of about 3.5 kg, while in the group of men who included exercise with the same high dose, this weight increase nearly doubled. Pope *et al.* (2000) found an increase of 3.0 kg following a typical bodybuilder regimen of increasing doses of testosterone cypionate from 150 mg·wk⁻¹ up to 600 mg·wk⁻¹ over 6 weeks. (They reported all of this weight gain as

lean mass on the basis of skinfold thicknesses that showed little change with androgen.) Although Forbes has suggested a dose-response relationship to lifetime exposure to androgens (Forbes 1985), these data suggest that supraphysiological doses of androgens provoke a specific weight increase as a threshold effect, after which mechanisms adjust and prevent further gains. If this were not true, one would expect all normal men to continue to gain weight from cumulative androgen exposure after the initial pubertal surge in testosterone, instead of reaching stable weights in the early 20s without further dramatic gains.

These increases in weight observed in controlled studies and clinical observations of high-dose androgen administration to normal men reflect only a portion of the apparent weight differences that have been estimated for anabolic steroid-using bodybuilders. In dedicated bodybuilders, Kouri *et al.* (1995b) found a difference in weight between steroids users and non-users of nearly 10 kg, with comparable estimates of adiposity between the groups (~12.5% body fat). A comparison of the data for 20 presteroid era Mr. America winners (1939–1959) to a group of popular modern bodybuilders indicated an estimated difference of 20 kg of mass, presumably lean mass. Changes in nutrition and health care over the past century have increased the lean mass of typical young US soldiers by nearly 10 kg (Friedl 2004). Thus, it would be reasonable to ascribe some of the weight gain in bodybuilders since the 1940s and 1950s to a combination of this improved nutrition, as well as exercise science techniques; however, Kouri's data provide at least a rough estimate of the upper limit of the mean gain that might be attributable to androgen use. The difference of 3–5 kg gains in controlled trials and 10 kg seen in androgen-using bodybuilders may reflect an effect of repeated cycles of use, as well as training and dietary interactions.

Characterizing changes in body composition

The nature of androgen-induced weight gain has never been adequately characterized. A key problem is that most studies have measured body composition using only one technique, with each

technique dependent on certain assumptions that may not hold true with anabolic steroid administration. Although the combined error of multiple techniques in a multicompartiment model of body composition is generally smaller than the biological variation in body compartments measured (Friedl *et al.* 1992a), multicompartiment models may also not resolve the question if steroid-induced changes confound the assumptions of these methods. For example, if a portion of the androgen response includes an increase in total body water relative to the total lean mass, as has been suggested but never properly tested (Freed *et al.* 1975; Hervey *et al.* 1976; Wilson 1988), this could produce significant errors in the estimated changes determined by each of the principal body composition techniques employed, by violating the assumptions about the composition of the lean compartment for each method. Underwater weighing assumes 1.1 g·cm⁻³ density of lean tissue, dual energy X-ray absorptiometry (DEA) assumes an attenuation coefficient based on normally hydrated soft tissue, potassium-40 depends on a fixed distribution in the lean compartment (66.6 mmol·kg⁻¹), and deuterium dilution assumes a fixed hydration level (usually 72%) of the lean mass. These might not be trivial errors. In semi-starvation of normal men, where hydration of the lean mass increases in a subclinical edema, DEA measures 3.5 kg more tissue than is actually present, based on simple scale weights (Friedl *et al.* 1994). Although speculative, a change in the opposite direction with rapid increase in body mass produced by androgens could also be accompanied by increased water retention. If this is the case, each of the body composition methods would be expected to incorrectly estimate the changes in the lean mass component of weight.

Hervey attempted to resolve the question in his studies of high-dose methandienone (100 mg·day⁻¹ for 6 weeks). Total body potassium measurements predicted that an average weight increase of 3.3 kg was composed of 6.3 kg lean mass gain and 2.5 kg fat loss. However, body density measured by underwater weighing predicted 2.4 kg lean mass gain and 0.9 kg fat gain, and skinfold thicknesses did not change (Hervey 1976). A second study with the same dosing produced comparable average

Fig. 35.3 Changes in body weight and lean and fat mass components in healthy young men administered $3 \text{ mg} \cdot \text{kg}^{-1} \cdot \text{wk}^{-1}$ testosterone enanthate for 12 weeks and following cessation of drug administration. LBM, lean body mass; W, weight. (From Forbes *et al.* 1992.)

weight gains of 3.6 kg and similar changes in the total body potassium (Hervey *et al.* 1981). This time, total body nitrogen was also measured by neutron activation analysis, with an estimate that if the increased body weight reflected new muscle, body nitrogen should increase by about 100 g. The measured increase was more than double this value, raising new questions about the nature of the increase.

Forbes *et al.* (1992) reported on a typical regimen of approximately $200 \text{ mg} \cdot \text{wk}^{-1}$ of TE for 12 weeks, showing an average weight gain of 4.1 kg (Fig. 35.3). Based on potassium-40 measurements, he estimated an increase in the lean mass component of 7.5 kg by the end of 12 weeks of drug administration. This was corroborated by urinary creatinine excretion that increased by an average $358 \text{ mg} \cdot \text{day}^{-1}$ (on a meat-free diet), corresponding to an estimated lean mass increase of 8.6 kg.

There is an apparent rapid loss from the lean mass compartment following androgen cessation. In this same study, Forbes *et al.* (1992) reported a prompt decline in weight to about 2.5 kg within the first 10 days following steroid cessation, and this new weight was maintained over the next 6 months (Fig. 35.3). The estimated lean mass declined to about half of the peak gain by 2 months following steroid cessation, and further declined over 6 months to just over 1 kg from the initial baseline.

This was balanced at stable weight by an assumed regain of fat weight following an initial average loss of 3.4 kg. The loss of at least some of the weight gain following steroid cessation is comparable to the observations in normal men in whom testosterone is artificially suppressed. Normal men artificially reduced to prepubertal levels of circulating testosterone for 10 weeks had a 2 kg loss of lean mass, with a comparable increase in fat mass, as measured by DEA (Mauras *et al.* 1998). This suggests a labile component of lean mass that has some dependence on threshold changes in androgen levels.

Several studies have used imaging or muscle biopsies to conduct morphological analyses on the cross-sectional area of muscle and muscle fibers. Histological analyses of muscle biopsies from the vastus lateralis of normal subjects following administration of TE $200 \text{ mg} \cdot \text{wk}^{-1}$ for 6 weeks was not able to demonstrate significant increases in muscle fiber diameter (Griggs *et al.* 1989), while two other studies using athletes found significant increases in muscle fiber area of this muscle (Alen *et al.* 1984; Kuipers *et al.* 1993). A more recent study found that TE 300 and $600 \text{ mg} \cdot \text{wk}^{-1}$ for 20 weeks in normal men with endogenous androgen suppression significantly increased the cross-sectional area of muscle fibers and myonuclear number in biopsies of the vastus lateralis, indicating an effect of androgen on muscle

hypertrophy; there was no significant change in the proportion of type I and type II fibers (Sinha-Hikim *et al.* 2002). This same study demonstrated dose-dependent increases in vastus muscle volume measured by magnetic resonance imaging (MRI), and an apparent dose-dependent increase in total lean mass at 300 and 600 mg·wk⁻¹ TE. In their earlier study, Bhasin *et al.* (1996) found significant increases in MRI-measured muscle cross-sections of both the triceps and quadriceps of the men receiving testosterone, whether or not they included exercise. However, no change was found for the exercise alone group, which supports the overall effect of androgens on muscle mass increase. New state-of-the-art techniques to quantify skeletal muscle should be of great value in terms of ease and precision for future studies (Gallagher *et al.* 1999).

Androgens increase muscle protein synthesis, but do not typically cause an increase in total body protein synthesis. Griggs *et al.* (1989) studied healthy men administered approximately 200 mg·wk⁻¹ TE for 12 wks and found typical increases in lean mass based on potassium-40 and creatinine excretion, accompanied by a 27% mean increase in muscle protein synthesis rates. The observed increases are therefore presumed to be a shift in the balance between synthesis and degradation rates, with an overall increase in turnover rates. Presumably, the effect is mediated directly through androgen receptors in the muscle, but this mechanism has not been well characterized, and there appear to be major differences in the androgen responsiveness of different muscles (Gustafsson *et al.* 1984; Hughes & Krieg 1988; Antonio *et al.* 1999). New studies of androgen-receptor signaling pathways in muscle are beginning to identify an inverse relationship between new muscle cell development and adipocyte development that appear to link androgen effects on fat and muscle shifts (Lee 2002), as has been previously suggested for steroid hormone actions in bone in the balance of osteoblasts and adipocytes. Other transgenic studies that use targeted overexpression of androgen receptor (Wiren *et al.* 2003) and muscle-specific IGF-I (Paul & Rosenthal 2002) in muscularly overdeveloped 'mighty mouse' animal models are likely to produce near-term breakthroughs in our understanding of bone, muscle and fat regulation by androgens,

as well as the essential role of estrogens in these effects.

Studies of regional fat tissue metabolism suggest that androgens reduce triglyceride accumulation in intra-abdominal fat, but do not have this effect on subcutaneous fat (Marin 1995; Marin *et al.* 1996), although testosterone treatment produces an increase in visceral fat in women (Elbers *et al.* 1997). An increase in lean mass might further influence body composition by changing energy requirements, but there is no apparent androgen-specific increase in energy metabolism. Welle *et al.* (1992) found a 7% increase in basal metabolic rate with TE (200 mg·wk⁻¹ for 12 weeks), and this increase could be completely accounted for by the increase in skeletal muscle mass. An informative study of the body composition changes was conducted using the 'Leydig clamp' model of Bhasin and his colleagues, with suppressed endogenous testosterone combined with sub- and supraphysiological doses of testosterone enanthate (25–600 mg·wk⁻¹ for 20 weeks) (Bhasin *et al.* 2001). Changes in lean men were assessed by DEA, including regional lean and fat estimates, and by multiple MRI slices of the thigh and abdomen (Woodhouse *et al.* 2004). The DEA data indicate increases in truncal and extremity lean mass with high doses, and increases in fat mass with subphysiological doses. MRI scans indicated increases in adipose tissue volumes in all regions assessed (intra- and subcutaneous abdominal, and intermuscular and subcutaneous thigh) at low doses, with less consistent reductions in adipose tissue volume at supraphysiological doses. These data provide confirmation of androgen-induced increases in lean components of body composition and decreases in fat mass.

Mechanisms of performance enhancement

Are observed strength gains only from increased muscle mass?

An increase in muscle size is associated with increases in strength, since maximal force production in a muscle is directly proportional to the cross-sectional muscle area. It has been suggested that androgens produce their main effects simply

through the increase in muscle size, without other changes in neuromuscular performance (Schroeder *et al.* 2003). There are other possible explanations for androgen-induced strength gains in athletes, including neuromuscular adaptations and muscle biochemical and physiological alterations, but these remain largely undefined. One of the first published strength studies in normal men involved four medical students given $50 \text{ mg} \cdot \text{day}^{-1}$ methyl testosterone along with creatine, and tested for changes in grip strength in a single-blind, crossover study with 3 weeks of steroid use (Samuels *et al.* 1942). No improvements in performance were observed. Among the difficulties in objectively assessing the direct effects of androgens on muscular strength are the variability inherent in strength tests, establishing appropriate controls for both individual experience and current training status, blinding the subjects to their treatment (because of obvious changes such as testicular volume), and the potentially important interactions with other factors that may also be influenced by androgens, such as motivation and training during the study.

Earlier studies with methandienone ($10 \text{ mg} \cdot \text{day}^{-1}$, or more, for 3–4 weeks) produced significant improvements of approximately 15% in one repetition maximum (1 RM) bench press performance, including some blinded tests and a mix of trained and untrained subjects, as previously reviewed (Haupt & Rovere 1984; Friedl 2000). Methandienone was quite consistent in increasing strength performance, although considerable discussion about the interactions with exercise has never been resolved (e.g. Freed *et al.* 1975; Hervey *et al.* 1981). With careful blinding, including a testosterone 'replacement' comparison dose group of TE ($100 \text{ mg} \cdot \text{day}^{-1}$), a high dose of TE ($300 \text{ mg} \cdot \text{day}^{-1}$ for 6 weeks) produced significant increases in elbow flexion and knee extension tests (Friedl *et al.* 1991). Despite equivalent gains in body weight in ND treatment groups 100 and $300 \text{ mg} \cdot \text{day}^{-1}$, there were no significant increases in strength. An increase in hip adduction was the only muscle strength measure that changed in untrained men receiving TE ($200 \text{ mg} \cdot \text{wk}^{-1}$ for 24 weeks) (Young *et al.* 1993). Bhasin *et al.* (1996) measured an increase in 1 RM bench press with TE ($600 \text{ mg} \cdot \text{wk}^{-1}$) and demonstrated that steroid and exercise each produced significant gains that were

additive in the steroid and exercise group (Fig. 35.4). In Bhasin's more recent dose-response study, TE (300 and $600 \text{ mg} \cdot \text{wk}^{-1}$) significantly increased 1 RM leg press (average increases of $\sim 75 \text{ kg}$) and leg power ($\sim 40\text{--}50 \text{ W}$ increase), while no changes were observed at replacement or lower doses (Bhasin *et al.* 2001). This corresponded to increases in thigh volume and muscle fiber size in these two groups. These strength changes did not appear to be dose-dependent. No changes were observed in leg press repetitions to failure ('fatigability') (Storer *et al.* 2003).

Separate from the effects of muscle cross-sectional area, effects on psychomotor enhancement have been suggested. Methandienone was reported to significantly shorten patellar reflex time in weight lifters (Ariel & Saville 1972), but an intensive study of a small group of elite steroid-using Finnish strength athletes showed no changes in psychomotor or motor speed tests compared to a control group of athletes (Era *et al.* 1988). Both groups improved physical performance during 24 weeks of training, without an apparent androgen effect (Alen *et al.* 1984).

Aggression and motivation

Testosterone has become synonymous with aggressive power. One of the most difficult aspects of studying androgen performance effects is ensuring that the subjects are blinded to the treatment, in part because many subjects perceive a change in their mental outlook when they are receiving high-dose androgens (Freed *et al.* 1975; Wright 1980). The change in mental status has been variously described as an increase in feelings of energy, a compulsive focus on winning their event, and complete disinhibition of aggressiveness, even to the point of murderous rage. Pope has reported extensively on the psychological effects of androgen supplementation for over a decade (e.g. Pope & Katz 1988, 1994). Pope's research team found significant neuropsychological effects in a thoughtful study designed to mimic the increase in androgen dose employed by many bodybuilders by stepping the weekly dose up from $150 \text{ mg} \cdot \text{wk}^{-1}$ to $300 \text{ mg} \cdot \text{wk}^{-1}$ to $600 \text{ mg} \cdot \text{wk}^{-1}$ (Kouri *et al.* 1995a; Pope *et al.* 2000). In this, and other studies reviewed by Pope and our own researchers (e.g. Hannan *et al.* 1991), individual manic or

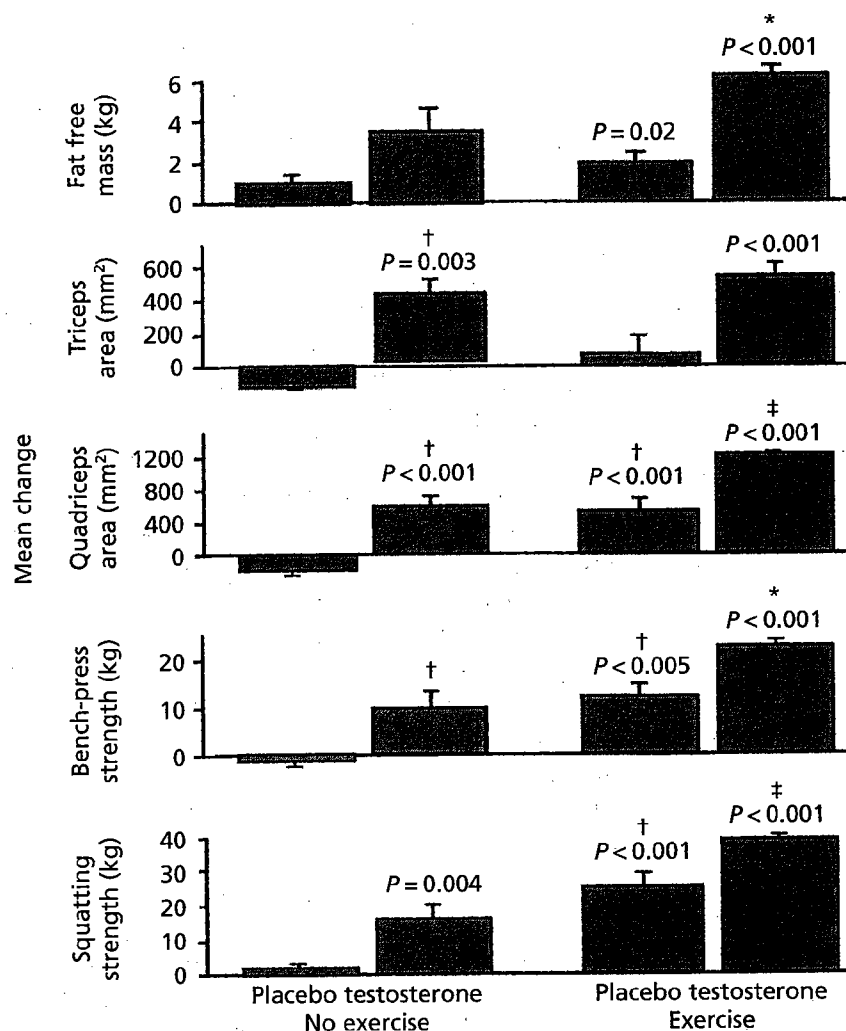

Fig. 35.4 Changes in body composition and strength measures in healthy young men administered placebo or 600 mg·wk⁻¹ testosterone enanthate for 20 weeks with or without an exercise program. (From Bhasin *et al.* 1996.)

hypomanic reactions have been observed, supporting the anecdotal case reports on manic behavior in androgen users. Pope *et al.* (2000) found significant responses in a specially designed test, the Point Subtraction Aggression Paradigm (PSAP), as well as the Young Mania Rating Scale and daily diary scores. The PSAP challenge test was particularly novel and appropriate in this study, probing individuals for a low threshold of aggressive response. A better understanding of who is at risk for the idiosyncratic reactions is vitally important to future human studies. Conceivably, the action is based on crossover activity to corticosteroid receptors (Janne 1990); psychotic episodes with high-dose corticosteroids have been well documented (Lewis & Smith 1983).

It is clear that almost irrational attitudes of invincibility provide a performance advantage, allowing athletes to withstand psychological fatigue and discomfort to persist and win. However, neurophysiologists have not completed the androgen connection between the behaviors, the neural circuits, and the biochemistry. Hannan *et al.* (1991) found an increase in dopamine metabolites in peripheral circulation of men administered high-dose androgens, suggesting the possibility of an interaction with the dopaminergic system, which has been implicated in a range of behaviors from highly focused, goal-directed behavior to psychosis. Indeed, androgens have been since demonstrated to increase HVA/DA ratios in the striatum of rats given one of four different androgens; methan-

dienone specifically increased dopamine synthesis (Thiblin *et al.* 1999). Hannan *et al.* (1990) had also shown in animal studies that stereotypic cage-exercising behavior was increased by androgen administration. Exercise effects on brain dopamine activity have been suggested to play a role in delaying exhaustion (Chaouloff *et al.* 1987) and might be interactive with androgens.

What do androgens do for endurance performance?

Androgens may provide endurance advantages through other non-psychological effects, including both energy availability and the oxygen-carrying capacity of the blood. These could be beneficial to performance of endurance athletes such as distance runners and cyclists. Earlier studies examined the effects of androgen supplementation on running and swimming performance. In an article that received high visibility in *Science*, Johnson and O'Shea (1969) reported that methandienone ($10 \text{ mg} \cdot \text{day}^{-1}$ for 3 weeks) increased maximal oxygen uptake by 15%, and significantly more than the gain in non-blinded control training partners. The same drug regimen failed to improve swim performance over that of a control group (O'Shea 1970), as did administration of oxandrolone ($10 \text{ mg} \cdot \text{day}^{-1}$ for 6 weeks) (O'Shea & Winkler 1970). Johnson *et al.* (1972) attempted to replicate the initial study reported in *Science*, measuring aerobic capacity after the same drug regimen of methandienone ($10 \text{ mg} \cdot \text{day}^{-1}$ for 3 weeks) or stanazolol ($6 \text{ mg} \cdot \text{day}^{-1}$ for 3 weeks), and a running training program, but found no change in maximal oxygen uptake or mile run time. Johnson speculated that the discrepancy in results could be explained by androgen-induced leg strength improvements that may have produced specific improvements in the bike test used in the original study, rather than a real increase in aerobic capacity. No further tests of androgens on aerobic performance in normal men have been reported.

There are plausible mechanisms to suggest androgen benefits to endurance performance. Androgens boost red blood cell production through stimulation of erythropoietin synthesis and secretion, direct stimulation of bone marrow hemato-

poiesis, and stimulation of iron incorporation into red blood cells. While androgen treatment has provided significant increases in hematocrit and hemoglobin in anemic patients (Neff *et al.* 1981), studies of high-dose androgen administration to normal men have not typically reported further increases (Mauss *et al.* 1975; Alen 1985; Kiraly 1988). However, Palacios *et al.* (1983) found a significant increase in red cell counts in normal men administered TE ($200 \text{ mg} \cdot \text{wk}^{-1}$ for 16 weeks), with modest increases in hematocrit and hemoglobin. Although rare, polycythemia has been reported in hypogonadal patients treated with androgens, usually in older patients. There may also be increases in blood volume (Wilson 1988), although this has not been verified in athletes. Thus, it is unclear that androgens boost hematological parameters in normal men, but if they did, there could be clear benefits to endurance performance. Erythrocyte infusions into normal men can substantially increase maximal oxygen uptake (Muza *et al.* 1987; Sawka *et al.* 1987). The downside is an increased risk of thromboembolytic injury such as stroke, especially with a potentiating effect of dehydration during intensive performance (Sawka *et al.* 1996). This is comparable to the risks that may be encountered by cyclists and other athletes using exogenous erythropoietin for performance enhancement (Adamson & Vapnek 1991).

Effects on the heart muscle and increases in stroke volume would theoretically also benefit endurance athletes. While the effects of androgens on left ventricular hypertrophy have been observed in strength athletes (e.g. McKillop *et al.* 1986), this has not been studied in endurance athletes, where steroid use appears to be less prevalent or far more covert.

It remains to be determined if androgens enhance lipolysis and energy availability for endurance performance. In one of the few studies to examine metabolic advantages, Guezennec *et al.* (1984a) tested endurance and metabolism of rats with elevated androgen levels during treadmill running for 7 h, but found no significant effects of testosterone other than a preservation of some of the glycogen stores. Other metabolic effects are potentially mediated through hormones such as IGF-I (Hobbs *et al.* 1993). Testosterone increases circulating IGF-I

levels, while nandrolone, which does not produce the same metabolites including estrogens, had no effect on total IGF-I levels. This suggests that there are differences in some of the biological actions of various synthetic anabolic steroids, determined by the receptor-binding affinities of the compounds and their metabolites. Androgens act to modify glucose disposal in normal men ($300 \text{ mg} \cdot \text{wk}^{-1}$ ND or TE) through non-insulin mechanisms (Hobbs *et al.* 1996).

Other hormonal responses to exercise, such as the acute rise in circulating growth hormone that occurs so dramatically in response to a serious strength athlete routine (more repetitions and short rests) compared to a body builder routine (higher weight and longer rests) (Kraemer *et al.* 1991), may also account for some of the effects currently ascribed to anabolic steroids. Growth hormone responds to acute metabolic signals, and like testosterone, specifically stimulates muscle protein and bone mineral accretion, and stimulates the release of IGF-I (Hindmarsh *et al.* 1997; Lee *et al.* 1997). It will be important to understand these interactions in the hormonal responses to exercise in future training studies in order to develop a systematic approach to science-based nutrition and training guidance.

Eunuchs may live longer, but do androgen-using athletes die sooner?

The health risks associated with androgen supplementation to normal men have been extensively reviewed and discussed elsewhere (e.g. Friedl 1990, 2000). In summary, the primary risks are a reversible reduction in sperm count and an accompanying testicular atrophy; hepatic adenoma that may be benign but may also result in hemorrhage and death; an adverse serum lipid profile with marked suppression of high-density lipoprotein (HDL)-cholesterol and unknown heart disease risk outcomes; changes in impulsivity and aggressiveness; skin changes including hair loss, oily skin, and acne; gynecomastia; and weight gain. Testosterone also plays a permissive role in prostate cancer, but a causative role remains to be demonstrated. From case reports of athletes using androgenic steroids, the majority of serious adverse health consequences

have been reported for bodybuilders. For example, in one review, 20 of the 28 case reports and most of the deaths involved bodybuilders (Friedl 2000).

Health benefits appear to accrue in replacement therapy in aging men, similar to hormone replacement therapy in women. These benefits include maintaining muscle mass and strength, which may be important in preventing injuries; maintenance of bone mass and prevention of male osteoporosis; antidepressant effects; and important effects on libido and motivation. Studies in the past decade indicate that androgens can increase glucose disposal separately from insulin-mediated mechanisms (Hobbs *et al.* 1996), as well as reduce intra-abdominal fat (Marin *et al.* 1995), both of which may be important in preventing type 2 diabetes. Reduction in fibrinolytic activity (Fearnley & Chakrabarti 1962) may reduce certain types of cardiovascular risks, perhaps countering effects such as the reduction in HDL-cholesterol, but conceivably increase hemorrhagic stroke risk. Although there is no defined disease of androgen excess in men, perhaps the effects of androgens are so ubiquitous that a wide variety of adverse health outcomes ranging from prostate cancer to heart disease are all diseases of androgen excess, just as being male is associated with shorter average lifespan. As a corollary of this, athletes that use androgenic steroids may be further trading lifespan for poorly defined performance advantages. Although eunuchs may have a longer average lifespan than normally virilized men (Hamilton 1948), it is unknown if the reverse is true. Epidemiological studies of retired athletes have been proposed but are fraught with complications, particularly in accurately ascertaining androgen administration histories and controlling for differences such as risk-taking behaviors in steroid users compared to non-steroid users.

Concern about the current increase in testosterone supplementation of older men at least has a tradeoff in disease prevention by reducing osteoporotic fractures and sarcopenia (that increases musculoskeletal injury risks). Replacement doses have been administered to many older men (> 45 years), and prescriptions for testosterone-replacement therapy have skyrocketed in the US in the past 5 years, providing a new cohort of men for studies

that are likely to provide new insights into the health consequences of androgen supplementation. There is also a growing database of experience with androgen administration to normal men from male contraceptive studies around the world. Other data on high-dose supplementation is emerging from efforts to sustain lean mass in muscular dystrophy and acquired immunodeficiency syndrome (AIDS) patients.

Conclusions

Androgenic steroids are banned at various levels of athletic competition, initially because of concerns about an uneven playing field, but then also out of concern for the health risks to the athletes. The greatest advantage is in bodybuilding in which huge muscle development is the goal, and the majority of case reports of serious health outcomes have centered on these athletes who are more likely to use very high doses that exceed levels that can be ethically studied. Other athletes appear to derive benefits from androgens for strength, endurance and overall psychological advantage. Prediction of the specific and individual effects of androgens is still uncertain. All of these compounds appear to have some positive musculotrophic effect, but the nature of this effect is still not well understood and almost certainly involves complex interaction with other hormones at the tissue level. Management of

diet and psychological stress are well-known factors in peak athletic performance, and it appears that endogenous testosterone levels can be markedly affected by these factors, making it a useful indicator of training status for males. The current thinking is that androgens may be useful in maintaining health and well-being in aging men as replacement therapy to prevent sarcopenia and osteoporosis. Supraphysiological doses that double or triple circulating levels have been tested in healthy young men for male contraception without remarkable effects other than modest weight gain. Higher doses, particularly when combined with exercise, may produce substantial gains in muscle mass and strength. Anecdotal reports of the use of extraordinarily high levels of androgenic steroids that extend well beyond the observations in controlled studies, involve primarily body builders and are associated with the majority of case reports of serious adverse health effects.

Doping expert thinks Landis result 'doesn't add up'

Associated Press

Tour de France champion Floyd Landis' results on a urine test that spots elevated levels of performance-enhancing testosterone are a mystery and "don't add up," a leading doping expert said Thursday.

Landis' team revealed Thursday that his urine sample last week showed "an unusual level of testosterone/epitestosterone."

Testosterone creams, pills and injections can build muscle and strength and improve recovery time after exertion when used over a period of several weeks, according to Dr. Gary Wadler, a member of the World Anti-Doping Agency and a spokesman for the American College of Sports Medicine.

But if Landis had been a user, earlier urine tests during the Tour would have been affected, too, Wadler said. Landis' first reported abnormal result was last Thursday, after his amazing come-from-behind performance in stage 17 of the race.

One-time use of steroids could result in an abnormal test, but it would have no effect on performance and could not account for Landis' astounding feat Thursday, "so something's missing here," Wadler said. "It just doesn't add up."

The test detects both testosterone and a related steroid called epitestosterone, which is not performance-enhancing. Both are produced by the body and are also made in synthetic form.

The usual ratio for both substances is about 1:1 or 2:1, Wadler said.

Suspicions for improper steroid use arise when the ratio climbs above 4 parts testosterone over 1 part epitestosterone, Wadler said. Officials have not said what ratio Landis' test showed.

Athletes who use performance-enhancing anabolic steroids often also take synthetic epitestosterone to equalize the ratio, said Charles Yesalis, a recently retired Pennsylvania State University professor and doping expert.

There is no medical use for synthetic epitestosterone; it is used "to cheat drug tests," Yesalis said.

Some men have naturally occurring high levels of testosterone and/or epitestosterone, but there is a sophisticated lab test called a carbon isotope ratio test that is often used to detect synthetic forms.

Alcohol can influence testosterone-epitestosterone levels, but more often in women than in men and it would be unlikely to have a huge effect, Wadler said.

Landis said in an interview during the Tour de France that he has had injections of cortisone, a medically used steroid drug to treat pain from a degenerating arthritic hip, but doctors said that would not affect his test results.

Corticosteroids "have zero impact" on the testosterone-epitestosterone test, Wadler said.

Expert's Q&A

In an exclusive interview with ESPN.com, Dr. Gary Wadler says that it's "extraordinarily unusual" for a "B" sample to exonerate a rider but that Floyd Landis' test results still don't make sense.

• For more of from Wadler, [Click here.](#)

GDC0054

The typical procedure for urine-testing of athletes involves taking two samples at the same time and bottling them separately. The "A" sample is tested first, and if it is normal the "B" sample is discarded. If the "A" sample shows elevated testosterone levels, the "B" sample is tested, and its results are used to confirm use of a banned substance, Wadler said.

The same "B" sample is also often subjected to the carbon isotope test, said Dr. Don Catlin, director of a World Anti-Doping Association-accredited Olympic lab at UCLA.

Landis' Phonak team suspended him pending results of the backup "B" sample.

Written Statement

GARY I. WADLER, M.D., FACP, FACSM, FACPM, FCP
Associate Professor of Clinical Medicine
New York University School of Medicine

Hearing on
Major League Baseball and the Use of performance-Enhancing Drugs

Before the
U.S. Congress House of Representatives Committee on Government Reform

March 17, 2005

Dear Mr. Chairman and Members of the Committee:

I am honored to appear here today and I appreciate the opportunity to testify. My name is Dr. Gary I. Wadler, and I am an Associate Professor of Clinical Medicine at New York University School of Medicine, a Fellow and former Trustee of the largest sports medicine and exercise science organization in the world, the American College of Sports Medicine, where I had chaired its Health and Science Policy Committee. In addition, I am a member of the Board of Stewards and former Vice-President of Women's Sports Foundation. I have served as a member of the Technical Advisory Committee of the CASA National Commission on Sports and Substance Abuse. At the local level, I serve as Chairman and President of the Nassau County Sports Commission.

I am the lead author of the internationally acclaimed text, *Drugs and the Athlete*, and the recipient of the 1993 International Olympic Committee's President's Prize for my work in the field of doping.

I have served as an expert on anabolic steroids to the United States Department of Justice, and since 1999, I have advised the Office of National Drug Control Policy on matters of doping.

I was intimately involved in the formation of the World Anti-Doping Agency, served on a number of its committees, including its Health, Medicine and Research Committee, its Therapeutic Use Exemption Committee, and its Athlete's Passport Committee. Currently, I represent the United States as a member of the WADA's Prohibited List and Methods Committee where, on occasion, I have served as Acting Chair.

I have no vested interest in testifying today other than to share my views with the Committee about the complex issue of Major League Baseball and the use of performance-enhancing drugs.

Since appearing before the United States Senate Committee on Commerce, Science and transportation in 1999 to discuss the use of performance-enhancing drugs in Olympic competition, there has been a sea change on many fronts.

At the federal level, we have witnessed great strides both nationally and internationally in the fight against doping.

The President highlighted the issues in his 2004 State of the Union, the Department of Justice has pursued the BALCO investigation, and the FDA removed ephedra and androstenedione from the store shelf.

Just last month, the recently enacted Anabolic Steroid Control Act of 2004 became effective adding numerous so-called steroid precursors to the list of anabolic steroids controlled under the federal Controlled Substances Act. This Act increased the government's commitment to education regarding the dangers of anabolic steroids while requiring a review of the federal sentencing guidelines for criminal offenses involving anabolic steroids.

The United States Government has also demonstrated its commitment through increased funding of several anti-doping initiatives. For example, just last year, \$7.5 million was appropriated to support the United States Anti-Doping Agency's (USADA) testing research and education programs. It was USADA that played a critical role in the BALCO revelations and in unmasking the numerous issues associated with the designer steroid, THG.

Internationally, the United States, with the Office on National Drug Control Policy at the helm, has played a leadership role in both the formation of WADA and in its ongoing governance and funding.

Specifically, in 2004, the United States Government contributed a historic and unprecedented \$1.45 million towards WADA's \$23 million budget (60% to research, 15% to out-of-competition testing, 15% to education, 10% for contingency) and that unprecedented level of commitment continues as reflected in the President's fiscal year 2006 budget.

WADA was created in November 1999 to support and promote fundamental values in sport. WADA was set up as a foundation under the initiative of the IOC with the support and participation of intergovernmental organizations, governments, public authorities and other public and private bodies fighting against doping in sport. The agency has equal representation from the Olympic Movement and from public authorities.

The United States is one of only five nations serving on WADA's Executive Committee. It chaired WADA's Ethics and Education Committee, and most recently, the United States Government has assumed a strong leadership position during the drafting of the anti-doping convention under the auspices of UNESCO.

With this as a backdrop, one must ask the question where have we gone astray with Major League Baseball and why should we care?

These questions can be addressed from many perspectives.

Perhaps the seminal moment in surfacing the current issue of performance-enhancing drug use baseball was in 1998 with the revelation that Mark McGwire had used androstenedione during his record-breaking 70 home run season. At the time, McGwire's use did not violate the laws of the land, nor the laws of baseball – both were to change.

The 2002 assertions of Jose Conseco and the late Ken Caminiti that steroid abuse was rampant in organized baseball were dismissed by many in baseball as being hyperbolic. However, last week Mr. Selig acknowledged that in 2001, that in fact, 11 percent of Minor League players had tested positive, and baseball's own 2003 "Survey Testing" had revealed that even with a very porous testing program, as many as 5 to 7 percent of Major League players had tested positive – the equivalent of two major league rosters.

Two weeks ago, we learned that in 2004, though employing a porous testing program, 1% to 2% tested positive, which still translates to an unacceptable numbers of users - between 12 and 24 league wide, the equivalent of a team to a team roster. The incidence would likely have been higher if the testing had been performed, as it should have been - year round, in and out of competition, random, no notice basis.

The incidence would likely have been higher if the testing had been performed, as it should have been - year round, in and out of competition, random, on a no notice basis.

To put these figures in perspective, compare Major League Baseball's statistics with those of WADA, where ½ percent of the 150,000 tests rigorously administered worldwide in 2003 were positive for steroids.

One can only conclude that the prior assertions of rampant steroid abuse in baseball were likely not hyperbolic.

Why should we care?

We should care for many reasons, but perhaps most notable, is that baseball, our national pastime, for better or for worse is a role model sport and likely contributes to the alarming abuse of anabolic steroids by teenagers. Just reflect on the enormous increase in sales of androstenedione (andro), the year after Mark McGwire broke Roger Maris' long-standing home run record.

The most recent data from the annual National Institute of Drug Abuse's Monitoring the Future survey reveals that in 2004, 3.4% of 12th graders have used these drugs at some time in their lifetime and as many as 1.9% of 8th graders have used them – very disturbing statistics.

And even more alarming is the perception amongst high school students that they are harmful has dropped significantly from 71% in 1992 to 56% in 2004.

And let me assure you from a public health perspective the abuse of these drugs is harmful both physically and behaviorally. Their abuse can lead to an array of physical problems, even with therapeutically prescribed doses, some predictable, some not, some permanent and some not.

Some adverse effects are visible to the naked eye, while others are not. If anabolic steroids are injected, the transmission of HIV and hepatitis B through shared needles and vials use is a very real concern.

Additionally, unlike almost all other drugs, the adverse effects of steroid based hormones share a unique characteristic -- their dangers may not be manifest for months, years and even decades.

With regard to physical side effects in males, their use may result in feminization with symptoms such as breast development, high-pitched voice, testicular atrophy, and impotency. This is because anabolic steroids may be converted in the body to estrogens in a process known as aromatization. The abuse of these drugs by women may result in their masculinization.

Both sexes can experience the following effects, which range from the merely unsightly to the life endangering. They include severe acne, bloating and rapid weight gain, clotting disorders, liver damage, premature heart disease and stroke, elevated total cholesterol and LDL levels with depressed HDL levels and increased tendinous injuries.

In adolescents, anabolic steroids can result in the premature closure of the epiphyses (growth centers in bone), such that the adolescent will never reach their genetically determined height.

The abuse of anabolic steroids can cause severe mood swings with marked irritability, depression, and with feelings of invincibility. Antisocial behaviors may be manifest by bouts of outright aggression commonly referred to as "roid rage".

Regular use of anabolic steroids can result in a dependency syndrome, which can result in the development of a profound depression that can lead to suicide.

But baseball's problem is not limited to steroids.

One can only wonder why baseball's new drug policy does not explicitly ban amphetamines.

It was amphetamine abuse that gave rise to both the controlled substances act of 1970, and to the development of the Olympic banned substances list in 1968, following the first recorded fatalities from performance-enhancing drugs, namely, amphetamines.

Amphetamines, which are stimulants, have an array of adverse effects associated with their use and abuse.

Acute side effects include: increased heart rate, increased blood pressure, reduced appetite and weight loss, insomnia, headaches, convulsions, hallucinations and paranoia, and death may also occur due to cerebral hemorrhages, heart attacks, heart rhythm abnormalities and heatstroke. Chronic side effects include: uncontrollable and abnormal movements of the face and jaw muscles called dyskinesias, compulsive and repetitive behaviors, paranoid delusions, systemic vascular disorders and nerve damage.

While ephedra is now banned in baseball subsequent to the heatstroke death of Steven Bechler and its being banned by the FDA, one should not lose sight of the fact that ephedra is closely related to the stimulant, amphetamine.

Why ephedra is banned by MLB and amphetamine is not remains an enigma.

The position that the player's association has taken with respect to amphetamines certainly leads one to suspect that they too are endemic in baseball.

Finally, a few words about MLB's new drug testing policy.

In my judgment, the policy as best we know it, can best be described as one of incrementalism - one designed to silence its critics, but one not designed to seriously rid professional baseball of the abuse of all performance-enhancing drugs.

And to be sure the devil is in the details. For example, while human growth hormone is on baseball's banned list, baseball will not conduct blood testing which is the only way it can currently be detected.

Doping is an exquisitely complex subject involving the interplay of numerous disciplines - chemistry, physiology, pharmacology, laboratory science, therapeutics and therapeutic exemptions, results management including sanctions, law, and least but not least, athlete's rights.

The interplay of these disciplines, as detailed in the International Standards of the World Anti-Doping Agency, has been approved by sporting bodies and governments worldwide. These Standards provide the blueprints and guideposts that are essential to an effective, transparent, and accountable anti-doping program.

In my opinion, the complexity of anti-doping far exceeds the capacity of baseball to design, implement and monitor an effective, transparent and accountable program.

It is beyond the scope of two attorneys and two physicians, one each from MLB and from the MLB Player's Association as called for in the 2003 agreement between the two entities.

It is noteworthy that the gold standard for anti-doping already exists.

It is embodied in the World Anti-Doping Code and its International Standards and Major League Baseball should embrace them.

Major League Baseball should heed the experience of the Olympic Movement, which recognized that its credibility, its very essence, was cracking under the weight of doping and so it passed the anti-doping baton to WADA and to national anti-doping agencies, such as USADA.

I am pleased to note that baseball has taken one significant step in that direction by contracting out its anti-doping laboratory services to a WADA accredited laboratory.

At a minimum, and now I am being very specific, as a next step, Major League Baseball should adopt the WADA List of Prohibited Substance and Methods in its entirety, as well as its existing testing protocols.

The List of Prohibited Substances and Methods is a continuously evolving product of countless man-hours experts, scientists and physicians from around the world. It is endorsed by sporting bodies, world wide, as well as by the governments of the world, including the United States.

While the potential of a two-year sanction for steroid abuse, as called for in the World Anti-Doping Code, may make baseball hesitant to embrace the Code, Major League Baseball should be aware that the Code calls for sanctions to be reduced in "exceptional circumstances", and provides for the possible reduction or elimination of the period of ineligibility in the unique circumstances where the athlete can establish that he had no fault or negligence in connection with the violation.

By adopting the World Anti-Doping Code, Major League Baseball would not be alone in so doing as a high profile professional sport. For example, currently men's professional tennis (ATP), soccer (FIFA), and professional cycling (UCI) are signatories to the Code.

Furthermore, United States Anti-Doping Agency, USADA, is in the best position to implement the best practices of doping control in Major League Baseball in conformity with the requirements set forth in the World Anti-Doping Code.

Finally, only when baseball demonstrates its unabashed commitment to drug free sport will it fully regain the confidence of its fans and once again deservedly become America's favorite pastime.

WADA panel member Wadler Q&A

ESPN.com

Dr. Gary Wadler, a member of the World Anti-Doping Agency's prohibited list and methods committee, spoke Thursday with ESPN.com about Floyd Landis, testosterone and testing.

Question: What do today's events mean for Floyd Landis and his victory in the Tour de France?

Answer: I would have been a lot happier if this had not appeared in the public domain until there was a confirmation of the "B" sample. Typically, the "B" sample confirms the "A" sample, but you don't know that until you do it. ... What we're hearing now is conjecture. If it is confirmed, it would be another very sad day in the long history of elite cycling.

Q: How often does a "B" sample differ from an "A" sample?

A: It's extraordinarily unusual. It's not common. The technology is quite sophisticated these days and you don't find that occurring very often. I'd be surprised if the "B" specimen doesn't confirm the "A," but until we know, we don't know. We have to be fair to athletes. They have due process. They are innocent until proven guilty. We should not be trying [anyone] until we know what the findings were, and he will have a chance to appeal this. We have to be a little bit cautious.

Q: Under World Anti-Doping Agency regulations, what is an acceptable testosterone-to-epitestosterone ratio?

A: It used to be 6-to-1. It's now 4-to-1. Most people are 1-to-1 or 2-to-1.

Q: Does a test positive for high levels of testosterone equate to a failed test?

A: The question for any given individual is, what does an abnormal or elevated ratio mean? Some people are born with [ratios] that are normally 4-to-1, or maybe 8-to-1. If they are consistently that way, week after week, there are ways to evaluate that. If the elevation exists and occurs naturally in that athlete, we can figure that out. This particular athlete -- Landis, in this case -- I'm sure has had multiple drug tests and a history of his testosterone to epitestosterone ratios, and if there's a sudden aberration, it sends up a red flag.

Q: For a cyclist, what's the benefit of elevated levels of testosterone? Why would a cyclist use it?

A: It's certainly not one of the first-line drugs one thinks of for racing. Steroids can increase strength and improve recovery time and prevent the breakdown of muscle, maybe make him more assertive and aggressive. All of those could have some positive attribute. But most steroids are given in cycles [6-12 weeks] and in context of working out in a gym with weights. It makes no sense to me why an athlete would take testosterone the day of a race when it doesn't work that way. It doesn't make sense in terms of the pharmacology of the drug, and it really doesn't have the attributes that would be attractive to a cyclist -- particularly one running the risk of violating anti-doping regulations.

Everybody knew the spotlight was on cycling. For eight years, the world has been watching cycling particularly closely. It would be the ultimate form of denial, or the ultimate sense of invincibility, to think you're going to evade that. And when the pharmacology of the drug doesn't really, in my judgment, seem like a drug of particular note to a cyclist, it doesn't really compute.

GDC0062

Q: When should we expect to learn the results of the "B" sample?

A: Certainly, with all that's going on, you could expect to see results within 24-48 hours.

What worries me is we will succumb to doping fatigue, that we will turn off our interest in doping, particularly the impact it has on young people. So much of our sports culture has doping issues around it, and people are getting tired of it. And they can't afford to get tired of it. The price is far too great for our society to develop a laissez-faire attitude. We cannot succumb to doping fatigue.

PART 14 ANTI-DOPING RULES OF THE UCI

(new rules entered into force on 13 August 2004)

INTRODUCTION

Pursuant to amendments adopted by the 115th session of the International Olympic Committee in July 2003, the Olympic Charter stipulates that in order to be recognized by the IOC, an International Federation must adopt and implement the World Anti-Doping Code (Rule 29).

To be eligible for a participation in the Olympic Games, a competitor, coach, trainer or official must respect and comply in all aspects with the World Anti-Doping Code (Rule 45).

As a consequence, at its meeting of 22-23 July 2004, the UCI Management Committee decided to accept the World Anti-Doping Code and to incorporate the Code in UCI's Regulations, as is done in these Anti-Doping Rules.

Terms in italiques are defined in appendix 1.

ANTI-DOPING RULES OF THE UCI

SUMMARY

| | Page |
|---|------|
| Chapter I SCOPE | 1 |
| Chapter II DOPING | 3 |

| Appendix 11: LIST OF MEDICINES TAKEN | 66 |
| Appendix 12: CODE OF SPORTS-RELATED ARBITRATION (CAS) | 67 |

Chapter SCOPE

- 1.** These Anti-Doping Rules shall apply to all *License-Holders*.

In-Competition Testing

- 2.** *Riders* participating in *International Events* shall be subject to *In-Competition Testing* under these Anti-Doping Rules.

Riders participating in *National Events* shall be subject to *In-Competition Testing* initiated and directed by the *National Anti-Doping Organization* of the country or any other organization or person so authorized by that *National Anti-Doping Organization*. *Doping Control* shall be governed by the anti-doping rules of the *National Anti-Doping Organization*.

Comment: As results from the above article, these Anti-Doping Rules do not apply at *National Events*.

- 3.** *In-Competition Testing* at *International Events* may be initiated and directed by the UCI or by the National Federation of the country or any other organization or person so authorized by the UCI. *Doping Control* shall be governed by these Anti-Doping Rules exclusively.

- 4.** If the UCI decides not to conduct any *Testing* at an *International Event*, the *National Anti-Doping Organization* for the country where the *Event* takes place, may initiate and conduct such *Testing* in coordination with and with the approval of the UCI or, if the UCI withholds its approval, with the approval of *WADA*. In such cases, *Doping Control* shall be governed by the anti-doping rules of that *National Anti-Doping Organization*.

- 5.** *Riders* shall be subject to *In-Competition Testing* at the Olympic Games, the Paralympic Games and events of *Major Event Organizations*.

Doping Control shall be governed by the rules of the International Olympic Committee, the International Paralympic Committee and the *Major Event Organizations* respectively. However, results management and the conduct of hearings shall be referred to the UCI as far as sanctions beyond *Disqualifications* from the event or the results of the event.

Out-of-Competition Testing

- 6.** *Riders* shall be subject to *Out-of-Competition Testing*.
- 7.** *Out-of-Competition Testing* may be initiated and conducted by the UCI or by the National Federation of the country or any other organization or person so authorized by the UCI.

UCI CYCLING REGULATIONS

Doping Control shall be governed by these Anti-Doping Rules exclusively.

8. Riders shall also be subject to *Out-of-Competition Testing* initiated and conducted by any other *Anti-Doping Organization* that is so authorized under the *Code*:
1. WADA;
 2. The International Olympic Committee or the International Paralympic Committee in connection with the Olympic Games or Paralympic Games;
 3. The *National Anti-Doping Organization* of the Rider;
 4. The *National Anti-Doping Organization* of any country where the Rider is present.

Doping Control shall be governed by the anti-doping rules of the *Anti-Doping Organization* concerned.

However, results management and the conduct of hearings from a test by the International Olympic Committee or the International Paralympic Committee shall be referred to the UCI as far as sanctions beyond *Disqualification* from the event or the results of the event.

- Comment:
- 1) As is expressed in the above article, any Rider may be tested *Out-of-Competition* by any of the above mentioned organizations, according to the rules of the organization conducting the test.
 - 2) National Federations may not initiate and conduct *Out-of-Competition* testing, including on their national level Riders, unless so authorized by the UCI or another *Anti-Doping Organization*.

Anti-doping violations where no *Sample* collection is involved

9. The UCI has jurisdiction for and these Anti-Doping Rules shall apply to any anti-doping violation committed by a *License-Holder* where no *Sample* collection is involved and that is discovered:
- (i) by the UCI, by one of its constituents or member Federations, by one of their officials, officers, staff members, members, *License-Holders*, or any other body or individual that is subject to the regulations of the UCI or one of its member Federations; or
 - (ii) by a body or individual that is not an *Anti-Doping Organization*.
10. If an anti-doping violation where no *Sample* collection is involved is discovered by another *Anti-Doping Organization*, the anti-doping rules of that *Anti-Doping Organization* shall apply.

However, if the violation is discovered by the International Olympic Committee or the International Paralympic Committee, results management and the conduct of hearings shall be referred to the UCI as far as sanctions beyond *Disqualification* from the event or the results of the event.

Results management concerning foreign or non-resident Riders

- 11.** Results management and the conduct of hearings for an anti-doping rule violation arising from a test by, or discovered by, a *National Anti-Doping Organization* involving a *License-Holder* that is not a citizen or resident of that country shall be administered by and under the rules of that *National Anti-Doping Organization*.

Unauthorized Testing

- 12.** If a *Rider* refuses a test by an *Anti-Doping Organization* that has no authority to test under these Anti-Doping Rules or under the *Code*, such refusal shall not constitute an anti-doping violation under these Anti-Doping Rules.
- 13.** If a *Rider* has been tested by an *Anti-Doping Organization* that has no authority to test under these Anti-Doping Rules or under the *Code* and the test results in an *Adverse Analytical Finding*, the UCI shall have jurisdiction and these Anti-Doping Rules shall apply.

General comment:

- 1) Under the *Code*, *National Federations* have no jurisdiction in *Doping Control*.

However, Anti-Doping Organizations having jurisdiction under the Code, may delegate jurisdiction to National Federations.

The involvement of National Federations in doping control at the international level is laid down in these Anti-Doping Rules.

National Federations and their respective National Anti-Doping Organization may agree on the Federation's involvement in Doping Control at the national level.

- 2) In addition to the obligations to submit to Testing pursuant to these Anti-Doping Rules and the *Code*, *Riders* may also be obliged to submit to Testing and be sanctioned for anti-doping violations pursuant to local anti-doping law.

Chapter DOPING

Definition of doping

- 14.** Doping is defined as the occurrence of one or more of the anti-doping rule violations set forth in article 15.

Anti-doping rule violations

15. The following constitute anti-doping rule violations:

1. The presence of a *Prohibited Substance* or its *Metabolites* or *Markers* in a *Rider's* bodily *Specimen*.

- 1.1. It is each *Rider's* personal duty to ensure that no *Prohibited Substance* enters his body. *Riders* are responsible for any *Prohibited Substance* or its *Metabolites* or *Markers* found to be present in their bodily *Specimens*. Accordingly, it is not necessary that intent, fault, negligence or knowing *Use* on the *Rider's* part be demonstrated in order to establish an anti-doping violation under article 15.1.

Warning:

- 1) *Riders must refrain from using any substance, foodstuff, food supplement or drink of which they do not know the composition. It must be emphasized that the composition indicated on a product is not always complete. The product may contain Prohibited Substances not listed in the composition.*
- 2) *Medical treatment is no excuse for using Prohibited Substances or Prohibited Methods, except where the rules governing Therapeutic Use Exemptions are complied with.*

- 1.2. Excepting those substances for which a threshold concentration is specifically identified in the *Prohibited List*, the detected presence of any quantity of a *Prohibited Substance* or its *Metabolites* or *Markers* in a *Rider's Sample* shall constitute an anti-doping rule violation.

- 1.3. As an exception to the general rule of article 15.1, the *Prohibited List* may establish special criteria for the evaluation of *Prohibited Substances* that can also be produced endogenously.

2. *Use or Attempted Use of a Prohibited Substance or a Prohibited Method.*

- 2.1. The success or failure of the *Use of a Prohibited Substance or Prohibited Method* is not material. It is sufficient that the *Prohibited Substance or Prohibited Method* was *Used or Attempted* to be *Used* for an anti-doping rule violation to be committed.

3. *Evading Sample collection or, after notification as authorized under these Anti-Doping Rules, refusing, or failing without compelling justification, to submit to Sample collection or, regarding the Riders referred to in article 122, to check in for Sample collection.*

4. *Violation of the requirements regarding Rider availability for Out-of-Competition Testing including failure to provide required whereabouts information and missed tests as set forth in article 86.*

5. *Tampering, or Attempting to tamper, with any part of Doping Control.*

6. *Possession of Prohibited Substances and Methods.*

- 6.1 Possession by a Rider at any time or place of a *Prohibited Substance* or a *Prohibited Method* referred to in article 15.6.3 below, unless the Rider establishes that the Possession is pursuant to a Therapeutic Use Exemption granted in accordance with chapter IV or other acceptable justification.
- 6.2 Possession of a *Prohibited Substance* or a *Prohibited Method* referred to in article 15.6.3 below, by Rider's Support Personnel in connection with a Rider, Event or training, unless the Rider's Support Personnel establishes that the Possession is pursuant to a therapeutic use exemption granted to a Rider in accordance with chapter IV or other acceptable justification.
- 6.3 In relation to Possession, the following categories of substances and methods of the *Prohibited List* are prohibited:

Categories of Prohibited Substances:

- S1. Anabolic agents
- S2. Hormones and related substances
- S3. Beta-2 agonists
- S4. Agents with anti-oestrogenic activity
- S5. Diuretics and other masking agents

Categories of Prohibited Methods:

- M1. Enhancement of oxygen transfer
- M2. Chemical and physical manipulation
- M3. Gene doping

7. Trafficking in any *Prohibited Substance* or *Prohibited Method*.
8. Administration or Attempted administration of a *Prohibited Substance* or *Prohibited Method* to any Rider, or assisting, encouraging, aiding, abetting, covering up or any other type of complicity involving an anti-doping rule violation or any Attempted violation.

Proof of doping

Burdens and standards of proof

16. The UCI and its National Federations shall have the burden of establishing that an anti-doping rule violation has occurred. The standard of proof shall be whether the UCI or its National Federation has established an anti-doping rule violation to the comfortable satisfaction of the hearing body bearing in mind the seriousness of the allegation which is made. This standard of proof in all cases is greater than a mere balance of probability but less than proof beyond a reasonable doubt. Where these Anti-Doping Rules place the burden of proof upon the Rider or other Person alleged to have committed an anti-doping rule violation to rebut a presumption or establish specified facts or circumstances, the standard of proof shall be by a balance of probability.

Methods of establishing facts and presumptions

- 17.** Facts related to anti-doping rule violations may be established by any reliable means, including admissions.
- 18.** WADA-accredited laboratories or as otherwise approved by WADA are presumed to have conducted *Sample* analysis and custodial procedures in accordance with the *International Standard* for laboratory analysis. The *Rider* may rebut this presumption by establishing that a departure from the *International Standard* occurred.

If the *Rider* rebuts the preceding presumption by showing that a departure from the *International Standard* occurred, then the UCI or the National Federation shall have the burden to establish that such departure did not cause the *Adverse Analytical Finding*.

- 19.** Departures from these Anti-Doping Rules, the *Procedural Guidelines* set by the Anti-Doping Commission or the *International Standard for Testing* which did not cause an *Adverse Analytical Finding* or other anti-doping rule violation shall not invalidate such findings or results. If the *Rider* establishes that departures from these Anti-Doping Rules, the *Procedural Guidelines* or the *International Standard* occurred during *Testing* then the UCI or its National Federation shall have the burden to establish that such departures did not cause the *Adverse Analytical Finding* or the factual basis for the anti-doping rule violation.
- 20.** Any *Anti-Doping Inspector*, *Medical Inspector*, commissaire or official shall draw up a detailed report of any anti-doping rule violation and of any incident, anomaly or irregularity concerning *Testing* which he may observe or which may be reported to him. He shall note the identity of any witnesses. Witness statements may be included in the report and countersigned by the witnesses. This report and all the supporting documentation must be sent without delay to the UCI Anti-Doping Commission.

Chapter THE PROHIBITED LIST

- 21.** These Anti-Doping Rules incorporate the *Prohibited List* which is published and revised by WADA as described in article 4.1 of the *Code*. The UCI will publish the current *Prohibited List* also in UCI's Official News Bulletin.

Comment:

- 1) the *Prohibited List* currently in force may also be found on UCI's website at www.uci.ch.
- 2) Most sections of the *Prohibited List* refer to categories of *Prohibited Substances* or *Prohibited Methods*, while only a limited number of these *Substances* or *Methods* are listed under that category; yet other *Substances* or *Methods* than those recited are prohibited as is indicated for the respective categories.

- 3) *The Prohibited List relates to a sports regulation. The Use or Possession of, and Traffic in, a number of substances on the List is also prohibited or regulated in the national laws of many countries. Criminal sanctions may apply. A substance or method that is not prohibited under the List may be prohibited or regulated under national law.*
22. Unless provided otherwise in the *Prohibited List* and/or a revision, the *Prohibited List* and revisions shall go into effect under these Anti-Doping Rules 3 (three) months after publication of the *Prohibited List* by WADA on WADA's website at www.wada-ama.org, without requiring any further action by the UCI.
23. WADA's determination of the *Prohibited Substances* and *Prohibited Methods* that are or will be included on the *Prohibited List* shall be final and not subject to challenge by a *License-Holder*.

IV

Chapter THERAPEUTIC USE EXEMPTION (TUE)

24. *Riders with a documented medical condition requiring the Use of a Prohibited Substance or a Prohibited Method must, prior to their participation in any International Event, obtain a Therapeutic Use Exemption (TUE) from the UCI, regardless of whether the Rider previously has received a TUE from his National Anti-Doping Organization.*

However, Riders of the juniors and masters categories shall obtain a TUE from their National Anti-Doping Organization or such authority as appointed by their National Anti-Doping Organization.

25. *Riders with a documented medical condition requiring the Use of a Prohibited Substance or a Prohibited Method who are not planning to participate in an International Event must, prior to their participation in any National Event, obtain a Therapeutic Use Exemption from their National Anti-Doping Organization or such authority as appointed by their National Anti-Doping Organization. The procedure for granting such TUE is governed by the rules of that National Anti-Doping Organization.*
26. The following articles of this chapter IV govern TUE's requested from the UCI.
27. A Therapeutic Use Exemption is granted according to a standard procedure (articles 38 - 45). For the *Prohibited Substances* or *Prohibited Methods* referred to in article 47, an abbreviated procedure is also available (articles 46 - 50).
28. Decisions regarding the grant, withdrawal and denial of TUE's are taken in the first instance by the Therapeutic Use Exemption Committee of the UCI.

Therapeutic Use Exemption Committee (TUEC)

29. The UCI shall appoint a committee of at least 3 (three) physicians to consider requests for TUE's: the Therapeutic Use Exemption Committee (TUEC).
30. The members of the TUEC, or at least 3 (three) of them, shall be physicians with experience in the care and treatment of athletes and a sound knowledge of clinical, sports and exercise medicine.
31. A majority of the members of the TUEC should not have any official responsibility in the UCI or a National Federation. All members of the TUEC will sign a conflict of interest agreement.
32. The TUEC may seek whatever medical or scientific expertise it deems appropriate in reviewing the circumstances of any application for a TUE.
33. In applications involving *Riders* with disabilities, advice shall be sought from an expert possessing specific experience with the care and treatment of athletes with disabilities, if no member of the TUEC possesses such experience.
34. Upon the UCI's receipt of a TUE application, the Chair of the TUEC shall appoint one or more members of the TUEC (which may include the Chair) to consider such application and render a decision promptly.

Criteria for granting a Therapeutic Use Exemption

35. A Therapeutic Use Exemption will be granted only in strict accordance with the following criteria:
 1. The *Rider* should submit an application for a TUE on a form provided by the UCI no less than 21 (twenty-one) days before participating in an *Event*.
 2. The *Rider* would experience a significant impairment to health if the *Prohibited Substance* or *Prohibited Method* were to be withheld in the course of treating an acute or chronic medical condition.
 3. The therapeutic use of the *Prohibited Substance* or *Prohibited Method* would produce no additional enhancement of performance other than that which might be anticipated by a return to a state of normal health following the treatment of a legitimate medical condition. The *Use* of any *Prohibited Substance* or *Prohibited Method* to increase "low-normal" levels of any endogenous hormone is not considered an acceptable therapeutic intervention.
 4. There is no reasonable therapeutic alternative to the *Use* of the otherwise *Prohibited Substance* or *Prohibited Method*.
 5. The necessity for the use of the otherwise *Prohibited Substance* or *Prohibited Method* cannot be a consequence, wholly or in part, of prior non-therapeutic *Use* of any *Prohibited Substance* or *Prohibited Method*.
 6. An application for a TUE will not be considered for retroactive approval except in cases where:
 - a. Emergency treatment or treatment of an acute medical condition was necessary, or
 - b. Due to exceptional circumstances, there was insufficient time or opportunity for a *Rider* to submit an application 21 (twenty-one) days prior to his participation in any *Event*, or the TUEC to consider the application prior to the *Rider's* participation in any *Event*.

UCI CYCLING REGULATIONS

- 36.** A TUE shall be denied on the ground of the impossibility or difficulty to control the dose, frequency, route of administration or any other aspect of the *Use of a Prohibited Substance or Prohibited Method*, that may produce enhancement of performance other than that allowed under article 35.3.
- 37.** The TUEC may submit the granting of a TUE to any conditions that it may specify.

Standard Therapeutic Use Exemption procedure

- 38.** A TUE will only be considered following the receipt of:
- (i) a legibly completed application form that complies with these Anti-Doping Rules and that must include all relevant information and documents, and
 - (ii) an application fee, the amount of which shall be set annually by the Management Committee.

Warning: *Any file that is not complete or not legible will not be considered as valid and will be returned to the sender.*

- 39.** The TUE application form(s), as set out in the *International Standard for Therapeutic Use Exemptions*, can be modified by the UCI Anti-Doping Commission to include additional requests for information, but no sections or items shall be removed.

- 40.** The TUE application form(s) shall be completed legibly, in English or French. Any information attached to the TUE application form shall be in English or French. If such information has been originally established in another language, the *Rider* shall attach the original document and a translation in English or French.

- 41.** A *Rider* may not apply to more than one *Anti-Doping Organization* for a TUE. The application must list any previous and/or current requests for permission to use an otherwise *Prohibited Substance* or *Prohibited Method*, the body to whom that request was made, and the decision of that body.

- 42.** The application must include a comprehensive medical history and the results of all examinations, laboratory investigations and imaging studies relevant to the application.

Any additional relevant investigations, examinations or imaging studies requested by the TUEC will be undertaken at the expense of the Rider.

- 43.** The application must include a statement by an appropriately qualified physician attesting to the necessity of the otherwise *Prohibited Substance* or *Prohibited Method* in the treatment of the *Rider* and describing why an alternative, permitted medication cannot, or could not, be used in the treatment of this condition.

The dose, frequency, route and duration of administration of the otherwise Prohibited Substance or Prohibited Method in question must be specified.

- 44.** The decision of the TUEC will be conveyed in writing to the *Rider* by the Anti-Doping Commission.

UCI CYCLING REGULATIONS

- 45.** Where a TUE has been granted, the *Rider* and *WADA* will be promptly provided with a certificate of approval for therapeutic use which includes information pertaining to the duration of the exemption and any conditions associated with the TUE. *WADA* will also be provided with all supporting documentation.

The *Rider* shall carry a copy of the certificate with him at all times and present it to the *Anti-Doping Inspector* at the time of *Testing*.

Abbreviated Therapeutic Use Exemption procedure

- 46.** It is acknowledged that some substances included on the *Prohibited List* are used to treat medical conditions frequently encountered in the athlete population. In such cases, a full application as detailed in article 35.4, and articles 38 - 45, is unnecessary. Accordingly an abbreviated process of the TUE is established.
- 47.** The *Prohibited Substances* or *Prohibited Methods* which may be permitted by this abbreviated process are strictly limited to the following: beta-2 agonists (formoterol, salbutamol, salmeterol and terbutaline) by inhalation and glucocorticosteroids by non-systemic routes.
- 48.** Approval for Use of one of the *Prohibited Substances* referred to in article 47 is effective upon receipt of a complete notification by the UCI.

The diagnosis and when applicable any tests undertaken in order to establish that diagnosis should be included (without the actual results or details).

Articles 39, 40 and 43 apply.

Notifications that are incomplete, illegible or do not comply with these Anti-Doping Rules, shall carry no exemption and shall be returned to the applicant.

- 49.** The UCI will advise *WADA* and the *Rider's* National Federation and *National Anti-Doping Organization* on receipt of a regular notification.

The UCI will provide *WADA* with the application for the TUE.

- 50.** A notification for a TUE will not be considered for retroactive approval except in cases where:
- emergency treatment or treatment of an acute medical condition was necessary, or
 - due to exceptional circumstances, there was insufficient time or opportunity for a *Rider* to submit, or the UCI to receive, the application prior to the *Rider's* participation in any *Event*.

Confidentiality of information

51. By applying for a TUE, the *Rider* provides consent for the transmission of all information pertaining to the application to members of the TUEC of the UCI and the TUEC of WADA and, as required, other independent medical or scientific experts, or to all necessary staff involved in the management, review or appeal of TUEs and for the decisions of the TUECs to be distributed to other relevant *Anti-Doping Organizations* under the provisions of the *Code*.
52. Should the *Rider* wish to revoke the right of the TUEC of the UCI or the TUEC of WADA to obtain any health information on his behalf, the *Rider* must notify his medical practitioners in writing of the fact. As a consequence of such a decision, the *Rider* will not receive approval for a TUE or renewal of an existing TUE.
53. Should the assistance of external, independent experts be required, all details of the application will be circulated without identifying the *Rider* and the medical practitioners involved in the *Rider's* care.
54. The members of the TUECs and the administration of the *Anti-Doping Organizations* involved will conduct all of their activities in strict confidence.

Duration of TUE

55. Each TUE will have a specified duration as decided upon by the TUEC. The duration shall be indicated in the certificate of approval for therapeutic use.

No TUE may have a duration of more than 1 (one) year. It may be renewed.

The TUE expires at the end of its duration.

Withdrawal of TUE

TUE granted under standard procedure

56. The TUEC of the UCI may review and withdraw the TUE at any time during the duration of the TUE.
57. The decision of the TUEC of the UCI withdrawing the TUE and the decision of WADA or the CAS reversing the granting of the TUE, shall take effect 14 (fourteen) days following notification of the decision to the *Rider*, unless the decision sets a shorter term.

TUE granted under abbreviated procedure

58. The TUEC of the UCI and the TUEC of WADA may review and withdraw the TUE at any time during the duration of the TUE.
59. A decision of the TUEC of the UCI or the TUEC of WADA withdrawing the TUE and a decision of the CAS reversing the granting of the TUE, shall take effect immediately following notification of the decision to the *Rider*.

The *Rider* will nevertheless be able to apply for a TUE in accordance with the standard procedure.

Results before withdrawal

- 60.** The withdrawal of a TUE and the decision reversing the granting of a TUE shall not apply retroactively. They shall not disqualify the *Rider's* results before the moment that the decision takes effect.

Results after expiry or withdrawal

- 61.** The Anti-Doping Commission, when conducting the initial review of an *Adverse Analytical Finding*, will consider whether the finding is consistent with expiry or withdrawal of the TUE.

Information

- 62.** The *Rider* and all relevant *Anti-Doping Organizations* shall be notified immediately of any decision withdrawing a TUE or reversing the granting of a TUE.

Review by WADA and appeal to the CAS

Review by WADA at the request of the Rider

- 63.** The *Rider* may request *WADA* to reverse the decision by which the TUEC of the UCI denies or withdraws a TUE.
- 64.** The *Rider* shall provide to the TUEC of *WADA* all the information for a TUE as submitted initially to the UCI, accompanied by the application fee that *WADA* may request. The TUEC of *WADA* will have the ability to request from the *Rider* additional medical information as deemed necessary, the expenses of which shall be met by the *Rider*.
- 65.** Until the review process has been completed, the decision of the UCI remains in effect.
- 66.** If *WADA* reverses the decision of the UCI, the reversal shall not apply retroactively. The *Rider* shall not be entitled to compensation by the UCI, in particular for missed participations in *Events*.
- 67.** The decision by *WADA* reversing the decision by the UCI may be appealed exclusively to the CAS by the UCI.
- 68.** If *WADA* confirms the decision by the UCI, the *Rider* may appeal the decisions by UCI and *WADA* exclusively to the CAS.
- 69.** The time limit for appeal with the CAS is 1 (one) month following receipt of the decision by *WADA*.

Review by WADA on its own initiation

- 70.** *WADA* may, on its own initiation, review and reverse at any time the decision by which the TUEC of the UCI denies or withdraws a TUE.
Articles 64 to 69 shall apply.
- 71.** *WADA* may, on its own initiation, review and reverse at any time the grant of a TUE by the UCI.

- 72.** The decision by WADA reversing the grant of the TUE by the UCI may be appealed exclusively to the CAS by the *Rider* or the UCI.
- 73.** The time limit for appeal with the CAS is 1 (one) month following receipt of the decision by WADA.

V

Chapter WHEREABOUTS INFORMATION

Registered Testing Pool

- 74.** The Anti-Doping Commission shall identify a UCI *Out-of-Competition Registered Testing Pool* of those *Riders* who are required to provide up-to-date whereabouts information to the UCI.

Comment: only the Riders included in the Registered Testing Pool are required to provide whereabouts information; however any Rider may be tested Out-of-competition at any time and at any place, even if he is serving a period of Ineligibility.

- 75.** The Anti-Doping Commission shall define the criteria for *Riders* to be included in the *Registered Testing Pool* and may also include *Riders* individually. The Anti-Doping Commission may revise the *Registered Testing Pool* from time to time as appropriate.
- 76.** A *Rider* continues to be included in the *Registered Testing Pool* and to be required to provide up-to-date whereabouts information to the UCI until he has been informed by the Anti-Doping Commission that he has been removed from the *Registered Testing Pool*. *Riders* that serve a period of *Ineligibility* continue to be included in the *Registered Testing Pool* and to be required to provide whereabouts information.
- 77.** A *Rider* who has given notice of retirement from cycling to the UCI may not resume competing at international level unless he notifies the UCI at least 6 (six) months in advance before he expects to return to international competition and is available for unannounced *Out-of-Competition Testing*, at any time during the period before actual return to competition.

Notice of retirement is effective only when the *Rider* has returned his license to his National Federation for that purpose.

Whereabouts information requirements

- 78.** The Anti-Doping Commission shall inform each *Rider* in the *Registered Testing Pool* via written notice that he has been included in the pool and must provide accurate whereabouts information in accordance with these Anti-Doping Rules and with any further instructions that the Anti-Doping Commission may deem appropriate.

UCI CYCLING REGULATIONS

The notice shall set the deadline for when the *Rider* is required to submit whereabouts information. This deadline shall be no earlier than 3 (three) weeks after sending the notice and no later than 2 (two) weeks prior to the start of the quarter.

The *Rider* shall confirm written receipt of such notice directly to the Anti-Doping Commission.

- 79. Each *Rider* in the *Registered Testing Pool* shall file quarterly reports with the Anti-Doping Commission on forms provided by the UCI which specify on a daily basis the locations and times where the *Rider* will be residing, training and competing.
- 80. Should a *Rider's* plans change from those originally submitted on the whereabouts information forms, the *Rider* shall immediately send updates of all information required in the form so that it is current at all times.
- 81. The *Rider* shall send his whereabouts information and updates to the Anti-Doping Commission by fax. The *Rider* may also provide whereabouts information and updates by electronic means, once an appropriate electronic system is in place and the *Rider* is informed accordingly.

Failure to comply

- 82. If whereabouts information is not received in time or is incomplete or inadequate or inaccurate, the Anti-Doping Commission shall provide a written warning to the *Rider*.

Should the *Rider* after the written warning not provide accurate whereabouts information within 7 (seven) days, the *Rider* shall be provided an additional written warning.

- 83. A failure to comply with a written warning shall be recorded, unless the Anti-Doping Commission accepts a reasonable justification.

- 84. Should the *Rider* not be located for *Testing* based on the most up-to-date information received from the *Rider*, the Anti-Doping Commission shall report the missed test, in writing, to the *Rider*.

The *Rider* shall have the right to provide a written explanation and to prove circumstances within 10 (ten) days from the sending of the report.

If the Anti-Doping Commission, after having considered the explanations and evidence provided by the *Rider*, finds the explanation not justified, it shall record a missed test and inform the *Rider*.

- 85. For each attempt to locate the *Rider* for *Testing*, the *Anti-Doping Inspector* shall visit all locations during the times specified by the *Rider* for that date and shall stay 1 (one) hour at each location (or until such moment that the *Rider* had announced to stay at that location, if earlier).

- 86. Should, in a rolling period of 18 (eighteen) months, a *Rider* receive 3 (three) recorded warnings for failure to provide accurate whereabouts information or a combination of failure to provide accurate whereabouts information and missed tests equals 3 (three), an anti-doping violation has occurred.

UCI CYCLING REGULATIONS

The Anti-Doping Commission will notify the *Rider's* National Federation and request it to initiate disciplinary proceedings for an anti-doping violation under article 15.4.

87. *Rider's* failure to provide accurate whereabouts information and/or missed tests under these Anti-Doping Rules may be combined with failures to provide accurate whereabouts information and/or missed tests recorded by other *Anti-Doping Organizations*, provided (i) the *Anti-Doping Organization* had authority under the *Code*, (ii) the Anti-Doping Commission was informed in time and (iii) the facts recorded by the *Anti-Doping Organization* constitute, to the satisfaction of the Anti-Doping Commission, a failure to provide accurate whereabouts information or a missed test under these Anti-Doping Rules.

Coordination with Anti-Doping Organizations

88. The UCI may collect whereabouts information also with the National Federations, WADA and other *Anti-Doping Organizations*.
89. The UCI will make the list of *Riders* in the *Registered Testing Pool* available to WADA. The UCI may make the list available to other *Anti-Doping Organizations*.
90. The UCI will submit all whereabouts information to WADA and WADA will make this information accessible to other *Anti-Doping Organizations* having authority to test the *Rider* as provided in article 8.
91. The UCI may provide whereabouts information to other *Anti-Doping Organizations* having authority to test the *Rider* as provided in article 8.

Confidentiality

92. The UCI shall maintain whereabouts information in strict confidence at all times and shall use it exclusively for purposes of planning, coordinating or conducting *Testing*. The UCI shall destroy the whereabouts information after it is not longer relevant for these purposes.
93. Under the *Code*, WADA and all *Anti-Doping Organizations* having accepted the *Code* are bound to the same obligations concerning confidentiality of whereabouts information.

However, the UCI shall not be liable for the use that WADA or any *Anti-Doping Organization* makes of whereabouts information, even if the information was provided by the UCI. The *Rider* has no claim against the UCI in this respect.

Obligations of National Federations

94. National Federations shall assist the UCI in obtaining whereabouts information concerning *Riders* as requested by the UCI.

- 95.** Each National Federation shall assist its *National Anti-Doping Organization* in establishing the latter's registered testing pool of national level *Riders*.

VI

Chapter TESTING

Procedural Guidelines

- 96.** The Anti-Doping Commission shall issue *Procedural Guidelines* for all aspects of *Testing* conducted under these Anti-Doping Rules.

Procedural Guidelines shall be in conformity with these Anti-Doping Rules and in substantial conformity with the *International Standard for Testing*.

Procedural Guidelines shall be binding upon their approval by the President of the UCI.

- 97.** In addition, the President of the Anti-Doping Commission and the *Anti-Doping Inspector* may at any time impose measures which are urgently required to ensure that *Testing* can take place.

Management

- 98.** Except as provided in articles 107, 108, 109 and 153, *Testing* is conducted by an *Anti-Doping Inspector* and a *Medical Inspector*.

(text modified on 1.01.07).

- 99.** The *Anti-Doping Inspector* is responsible for the on site management of the *Testing*.

- 100.** For World Championships, the Management Committee shall appoint a UCI official doctor who shall be a member of the Anti-Doping Commission or a doctor proposed by the Anti-Doping Commission. The UCI official doctor is responsible for the on site management of the *Testing* at World Championships. He may act as *Medical Inspector*.

- 101.** The *Anti-Doping Inspector* is appointed by the Anti-Doping Commission or, in case of urgency, by its President or his replacement.

However, the *Anti-Doping Inspector* shall be appointed by the National Federation of the country in the following cases:

1. for *Post-Competition Testing* at Events on the B list according to article 112, c;
2. for *Post-Competition Testing* at Events at which the National Federation is authorized to test by the UCI according to article 3;

UCI CYCLING REGULATIONS

3. for *Out-of-Competition Testing* that the National Federation is authorized to conduct on *Riders* by the UCI.
- 102.** The *Medical Inspector* shall be responsible for the sample taking as described in these Anti-Doping Rules and in the *Procedural Guidelines*.
- 103.** The *Medical Inspector* for *In-Competition Testing* shall be a doctor.
- 104.** For *In-Competition Testing*, the *Medical Inspector* shall be appointed by the organizer's National Federation. The race doctor shall not be appointed as *Medical Inspector* for *Testing* at the *Event*.
- 105.** The organizer's National Federation shall also appoint a female nurse to attend the delivery of the sample from women if the *Medical Inspector* is a man and a male nurse to attend the delivery of the sample from men if the *Medical Inspector* is a woman.
- 106.** If needs be and without prejudice to the responsibility of the National Federation, the *Anti-Doping Inspector* may appoint a *Medical Inspector* and/or a nurse on the spot.
- 107.** For *Out-of-Competition Testing*, a *Medical Inspector* is not required to be appointed and the tasks and responsibilities otherwise entrusted to the *Medical Inspector* shall be carried out by the *Anti-doping Inspector*.

(text modified on 1.01.07).

- 108.** The Anti-Doping Commission and, in the case of article 7, the National Federation may arrange to have *Out-of-Competition Testing* carried out by another *Anti-Doping Organization* or by a specialist institute or company. The tasks of the *Anti-Doping Inspector*, *Medical Inspector* and person witnessing the delivery of the sample shall be carried out by the persons or the single person designated for such a purpose by the organization, institute or company in question.

(text modified on 1.01.07).

- 109.** Article 108 shall also apply where a National Federation is authorized to conduct *In-Competition Testing*, unless decided otherwise by the Anti-Doping Commission.
- 110.** The *Medical Inspector* may be assisted by another doctor or a nurse.
- 111.** For the taking of *Samples* other than urine *Samples* any person with the appropriate qualifications may be appointed.

Post-Competition Testing

- 112.** A *Post-Competition Testing* session shall be organized at the following *Events*:
 - a) World Championships, Continental Championships and Regional Games, as per the *Procedural Guidelines*;

- b) World record and continental record attempts;
- c) Any other *Event* designated by the Anti-Doping Commission; these *Events* shall be included on the A list or the B list, depending on whether the *Anti-Doping Inspector* is appointed by the Anti-Doping Commission (A list) or the National Federation of the organizer (B list), in accordance with article 101.

113. At stage races where *Testing* takes place, a *Post-Competition Testing* session shall be organized following each stage unless determined otherwise by the Anti-Doping Commission.

114. At six-day events, *Post-Competition Testing* shall be organized on a minimum of 2 (two) days.

National Federation

115. The National Federation of the organizer of the *Event* shall be responsible for the practical aspects of the organization of the *Post-Competition Testing* session, including the obligations on the organizer. It must insure that all staff and all infrastructure and equipment are available so that *Testing* can be carried out in accordance with these Anti-Doping Rules and the *Procedural Guidelines*.

116. Without prejudice to the application of article 12.1.008 of the Cycling Regulations to the organizer, in the event of negligence in the practical organization of the *Testing* session the National Federation of the organizer shall be liable to a fine not exceeding 10'000 CHF. In *Events* which last more than one day, the fine may be multiplied by the number of days for which the negligence continues.

117. If, as a result of negligence during the practical organization of the *Testing* session, the *Anti-Doping Inspector* appointed by the Anti-Doping Commission is unable to carry out his mission properly, the National Federation and the organizer shall be jointly and severally liable to repay his expenses.

Doping control station

118. Premises suitable for the taking of *Samples* must be provided in the immediate vicinity of the finish line. The location must be clearly signposted from the finish line.

119. Should the circumstances justify it, the Anti-Doping Commission may grant an exemption to the requirement of immediate vicinity. The organizer or his National Federation must submit a fully documented request to the Anti-Doping Commission no later than one month before the start of the *Event*.

120. At the request of the *Anti-Doping Inspector*, the organizer shall appoint an official to protect the entrance of the doping control station and prevent access by persons not involved in *Testing*.

Selection of Riders to be tested

121. The *Riders* to be tested shall be as designated in the *Procedural Guidelines*.

The Anti-Doping Commission may also issue confidential instructions to the *Anti-Doping Inspector* for the selection of *Riders* to be tested in a particular *Event*.

UCI CYCLING REGULATIONS

- 122.** For each *Competition* or *Race* for which a *Post-Competition Testing* session is organized, the *Anti-Doping Inspector* shall draw lots for a first and a second reserve *Rider* who will be subjected to testing in that order if a *Rider* drawn by lot is required to undergo tests as a result of his placing or if a *Rider* meets two criteria for selection simultaneously or if one such *Rider* is unable for practical reasons to undergo *Sample* taking, so that the number of tests called for by the Anti-Doping Commission is carried out.

The reserve *Riders* must check in for *Sample* collection within the prescribed time limit, even if they would not be required to submit to *Sample* collection.

- 123.** The circumstances that another *Rider* was tested than those selected according to the *Procedural Guidelines* or the instructions of the Anti-Doping Commission, shall not invalidate the *Testing* of that *Rider*.

Notification of Riders

- 124.** Any *Rider* including any *Rider* who has abandoned the *Race*, shall be aware that he may have been selected to undergo *Testing* after the *Race* and is responsible for ensuring personally whether he is required to appear for *Sample* collection.

To this end, the *Rider*, immediately after finishing or abandoning the *Race* shall locate and proceed to the place where the list of *Riders* who are required to appear for *Sample* collection, is displayed and consult the list.

Riders who participate in time trials shall consult the list after the last *Rider* finishes his ride.

- 125.** The organizer and the *Anti-Doping Inspector* shall ensure that a list of the *Riders* who are required to appear for *Sample* collection shall be displayed at the finish line and at the entrance of the doping control station before the finish of the winner.

- 126.** At track *Events*, one copy of the list shall be displayed at the entrance of the access tunnel when leaving the track center and the other copy shall be displayed at the entrance of the doping control station.

At trial and indoor *Events*, one copy of the list shall be displayed where the *Riders* leave the course or field after having finished their performance and the other copy shall be displayed at the entrance of the doping control station.

- 127.** *Riders* shall be identified on the list by their name or their race number or their place in the ranking.

- 128.** No *Rider* may take the absence of his name, race number or placing from the displayed list as excuse if he is identified in another manner or if it is established that he had learnt in another way that he was required to appear for *Sample* collection.

- 129.** At all times a *Rider* may be called for *Testing* at a *Post-Competition Testing* session in the same way as for *Individual Testing*.

Comment: In addition to displaying the list of Riders to be selected, additional forms of notification are sometimes used such as audio announcements via "Radio Tour" or at the finish venue. The absence of such additional forms of notification may never be interpreted as an indication that no Testing will take place and is no excuse for failing to submit to Sample taking.

When a Rider does not appear for Sample taking, there is no obligation for the Anti-Doping Inspector, the organizer or anyone else to try to contact or notify the Rider.

- 130.** An escort shall remain close to the Rider and observe him at all times, and accompany him to the doping control station. The absence of an escort cannot be pleaded as a defense.

Time-limit for attendance

- 131.** Each Rider to be tested must present himself at the doping control station within 30 (thirty) minutes of finishing the Race or, where appropriate, within 30 (thirty) minutes of the end of an official ceremony in which he has taken part. For a Rider required to attend a press conference under a provision of the regulations, the deadline shall be extended to 50 (fifty) minutes.

- 132.** A Rider who has abandoned the Race must attend within 30 (thirty) minutes of the finishing time of the last classified Rider.

- 133.** A Rider who has to take part in another Race on the same day may, within the time-limit set as above, ask permission from the Anti-Doping Inspector to submit to Sample taking after the other Race. The inspector shall decide whether the test should take place immediately or following the other Race.

Report

- 134.** For each Post-Competition Testing session, the Anti-Doping Inspector shall draw up a report in which he shall attest that Testing complies with these Anti-Doping Rules and the Procedural Guidelines or note the irregularities that he observed.

Within 48 (forty-eight) hours of the dispatch of the Samples to the laboratory this report must be sent to the Anti-Doping Commission.

Individual Testing

- 135.** Individual Testing may be organized In-Competition and Out-of-Competition, at any time and any place and without notice.

- 136.** The Anti-Doping Commission shall determine the place and time and the Riders to be tested or authorize the National Federation to do so.

UCI CYCLING REGULATIONS

- 137.** *Individual Testing* may be carried out at any place where the privacy of the *Rider* is ensured and that is used solely as a doping control station for the duration of the *Sample* collection session.

Sample taking shall be carried out in the best possible manner under the circumstances given and as discreetly as possible.

Notification of Riders

- 138.** *No Advance Notice Testing* shall be the notification method for *Individual Testing* wherever possible.

- 139.** *Riders* shall be called for *Individual Testing* using a notification form.

- 140.** The *Anti-Doping Inspector* shall notify the *Rider* in person. When the notification takes place *In-Competition*, the *Rider* may also be notified via his team manager or club representative.

- 141.** The *Rider* or his team manager or club representative shall sign the original notification form as proof of receipt. If the *Rider* or his team manager or club representative refuses to sign that he has been notified or evades notification, the *Anti-Doping Inspector* shall note this on the form and inform the *Rider* of the consequences of failing to comply if possible.

- 142.** During stage races and World Championships, the team manager or club representative must always be in a position to indicate where his *Riders* are in order that they may be contacted as quickly as possible.

Team managers or club representatives who give incorrect information, refuse to give information or obstruct *Testing* in any other way shall commit an anti-doping violation under article 15.5 (*Tampering or Attempting to tamper*).

- 143.** The *Rider* notified of *No Advance Notice Testing* shall remain within sight of the *Anti-Doping Inspector* or a chaperone at all times from the moment of in-person notification until the completion of the *Sample* collection procedure. If it was not possible for the *Anti-Doping Inspector* to observe the *Rider* or to have the *Rider* chaperoned at all times, this shall be recorded by the *Anti-Doping Inspector*.

- 144.** The time-limit within which the *Rider* is to appear for *Sample* taking shall be set by the *Anti-Doping Inspector*, taking account of the circumstances. *Sample* taking shall be carried out as soon as possible and, except in abnormal circumstances, not later than one hour of the *Rider* (or his team manager or club representative) receiving notification. The *Anti-Doping Inspector* may accept a request from a *Rider* to perform urgent preferential activities before proceeding to the doping control station. The request shall be rejected if it will not be possible for the *Rider* to be continuously observed.

Common rules for Post-Competition Testing and Individual Testing

Attendants

- 145.** The *Rider* may be accompanied by a person of his choice and an interpreter during the *Sample* collection session except when the *Rider* is passing an urine *Sample*.

- 146.** A *Minor Rider*, and the witnessing doctor or nurse are entitled to have a representative observe the doctor or nurse when the *Minor Rider* is passing a urine *Sample*, but without the representative directly observing the passing of the *Sample* unless requested to do so by the *Minor Rider*.
- 147.** When applicable under the *Independent Observer Program*, WADA Independent Observers may attend the *Sample* taking session. WADA Independent Observers shall not directly observe the passing of the *Sample*.
- 148.** The *Rider*, his attendant and the interpreter and any objects they bring with them may be searched.

Time limit for *Sample* taking

- 149.** When a *Rider* does not report to the doping control station within the time-limit, the *Anti-Doping Inspector* shall use his judgment whether to attempt to contact the *Rider*.
- 150.** If a *Rider* foresees that he might be prevented from reporting within the time-limit, he shall try, by all available means, to inform the *Anti-Doping Inspector*.
- 151.** At a minimum, the *Anti-Doping Inspector* and the *Medical Inspector* shall wait 30 (thirty) minutes after the time-limit before departing.
- 152.** If the *Rider* reports to the doping control station after the minimum waiting time and prior to the departure of the *Anti-Doping Inspector* and the *Medical Inspector*, they shall if at all possible proceed with collecting a *Sample* and shall document the details of the delay in the *Rider* reporting to the doping control station.
- 153.** If only one of the *Anti-Doping Inspector* or *Medical Inspector* is still present, *Sample* collection performed by only one of them may take place if both the *Rider* and the *Anti-Doping Inspector* or *Medical Inspector* so agree.
- 154.** The *Sample* taking may not be delayed, for example to await the arrival of the *Rider's* attendant or interpreter.
- 155.** The *Rider* shall only leave the doping control station if authorized by the *Anti-Doping Inspector* and under continuous observation by the *Anti-Doping Inspector* or a chaperone. The *Anti-Doping Inspector* shall consider any reasonable request by the *Rider* to leave the doping control station, until the *Rider* is able to provide a *Sample*.

If the *Anti-Doping Inspector* gives approval for the *Rider* to leave the doping control station, the *Anti-Doping Inspector* shall agree with the *Rider* on:

- a) The purpose of the *Rider* leaving the doping control station; and
- b) The time of return (or return upon completion of an agreed activity).

The *Anti-Doping Inspector* shall document this information and the actual time of the *Rider's* departure and return.

UCI CYCLING REGULATIONS

- 156.** The *Anti-Doping Inspector* and *Medical Inspector* shall continue the doping control session until the *Rider* delivers the *Samples* required under these Anti-Doping Rules.
- 157.** Should the *Rider* leave the doping control station, before the *Sample* is taken, he shall be considered to have refused the test and shall incur the sanctions set out in article 15.3.
- 158.** Should a *Rider* leave the doping control station after the *Samples* are taken but before all the formalities are completed, the *Testing* shall be deemed valid.
- 159.** Should the *Anti-Doping Inspector* or the *Medical Inspector* discharge a *Rider* or terminate the *Testing* session before the *Rider* has been tested, the *Rider* concerned shall be considered as not to have been selected for *Sample* taking and shall not have committed an anti-doping violation for having left the doping control station.
- 160.** The events covered by articles 149 to 159 shall be recorded.

Anomalies

- 161.** Any behavior by the *Rider* and/or persons associated with the *Rider* or anomalies with potential to compromise the *Sample* collection shall be recorded.
- 162.** If there are doubts as to the origin or authenticity of the *Sample*, the *Rider* shall be asked to provide an additional *Sample*. If the *Rider* refuses to provide an additional *Sample*, this shall be recorded by the *Anti-Doping Inspector*. A refusal to provide an additional *Sample* shall be considered as a refusal to submit to *Sample* collection under article 15.3.

Documentation

- 163.** The *Anti-Doping Inspector* shall provide the *Rider* with the opportunity to document any concerns he may have about how the session was conducted.
- 164.** The *Rider* and the *Anti-Doping Inspector* shall sign appropriate documentation to indicate their satisfaction that the documentation accurately reflects the details of the *Rider's Sample* collection session, including any concerns recorded by the *Rider*. The *Rider* representative shall sign on behalf of the *Rider* if the *Rider* is a *Minor*. Other persons present who had a formal role during the *Rider's Sample* collection session may sign the documentation as a witness of the proceedings.

The *Anti-Doping Inspector* or the *Medical Inspector* shall provide the *Rider* with a copy of the records of the *Sample* collection session that have been signed by the *Rider*.

- 165.** By appending his signature on the *Testing* form, the *Rider* confirms that, subject to any concern recorded by the *Rider*:
 - 1. the *Testing* was conducted in accordance with applicable standards and regulations;
 - 2. any subsequent complaint is excluded;
 - 3. he received a copy of the *Testing* form.

Reporting

- 166.** The UCI will report all *Testing* conducted under these Anti-Doping Rules to WADA, including the name of the *Rider*, the date and place of the test and whether the test was *In-Competition* or *Out-of-Competition*.

National Federations that conduct *Testing* under these Anti-Doping Rules shall report all *Testing* to the UCI immediately after *Testing*.

WADA shall make the information accessible to the *Rider*, the *Rider's* National Federation, National Olympic Committee or National Paralympic Committee, *National Anti-Doping Organization* and the International Olympic Committee or International Paralympic Committee.

Property of Samples

- 167.** The *Samples* collected under these Anti-Doping Rules shall become the property of the UCI upon collection.

Samples for screening

- 168.** *Riders* shall be also subject to *Sample* taking for screening purposes.
- 169.** The UCI may use for screening purposes any relevant information collected, received or discovered, including blood *Samples* or other non-urine *Samples* collected pursuant to other regulations. The UCI is not obliged to justify the reason why the *Rider* was targeted and what information was used for screening or targeting.

Sample collection equipment

- 170.** *Sample* collection equipment systems shall be used that:
1. have a unique numbering system incorporated into all bottles, containers, tubes or any other item used to seal the *Rider's Sample*;
 2. have a sealing system that is tamper evident;
 3. ensure the identity of the *Rider* is not evident from the equipment itself;
 4. ensure that all equipment is clean and sealed prior to use by the *Rider*.

Sample transport

- 171.** The *Anti-Doping Inspector* shall be responsible for:
- storing the *Samples* prior to transport;
 - sending the *Samples* with accompanying documentation to the laboratory;
 - sending the *Sample* collection session documentation for the laboratory and the Anti-Doping Commission in accordance with the *Procedural Guidelines*.

Costs of Testing

- 172.** The costs of *In-Competition Testing* initiated and directed by the UCI shall be borne by the organizer of the *Event*.

UCI CYCLING REGULATIONS

- 173.** The costs of *Out-of-Competition Testing* directed by the UCI shall be borne by the UCI. The costs of *Out-of-Competition Testing* directed by a National Federation so authorized at its request, shall be borne by that National Federation.
- 174.** The National Federation of the *Rider* shall be responsible for the costs of the B *Sample* analysis.
- 175.** Should a *Rider* be sanctioned following *Testing*, he shall bear the costs incurred for *Out-of-Competition Testing* and B *Sample* analysis.

Analysis of Samples

- 176.** *Samples* shall be sent for analysis only to WADA-accredited laboratories or as otherwise approved by WADA. The choice of the WADA-accredited laboratory (or other method approved by WADA) used for the *Sample* analysis shall be determined exclusively by the Anti-Doping Commission.
- 177.** When specific circumstances so justify, the Anti-Doping Commission may request that part of a *Sample* is analyzed in a second laboratory.
- 178.** *Doping control Samples* shall be analyzed to detect *Prohibited Substances* and *Prohibited Methods* identified on the *Prohibited List* and other substances as may be directed by WADA pursuant to the Monitoring Program described in Article 4.5 of the *Code*.
- 179.** Laboratories shall analyze doping control *Samples* and report results in conformity with the WADA *International Standard for Laboratory Analysis*.
- 180.** Subject to articles 168 and 169, no *Sample* may be used for any purpose other than the detection of substances (or classes of substances) or methods on the *Prohibited List*, or as otherwise identified by WADA pursuant to its Monitoring Program, without the *Rider's* written consent.
- 181.** The laboratory shall report any *Adverse Analytical Findings* to the Anti-Doping Commission and WADA or, if the *Adverse Analytical Finding* concerns World Championships, to the UCI official doctor and WADA.

VII

Chapter RESULTS MANAGEMENT

- 182.** Results management under these Anti-Doping Rules, including results management from a test by a National Federation pursuant to articles 3 and 7, shall be conducted by the UCI's Anti-Doping Commission.
- 183.** The Anti-Doping Commission shall refer results management concerning a *License-Holder* who usually does not participate in *International Events*, to the *License-Holder's* National Federation, who shall conduct results management in substantial conformity with this chapter.

Review

- 184.** If after receiving a test analysis report, an inspector's statement, a referral by another *Anti-Doping Organization*, or any document or information regarding a possible anti-doping violation, the Anti-Doping Commission considers that no anti-doping violation or any other breach of these Anti-Doping Rules has taken place, then the case shall be taken no further.

This decision shall not be definitive and the Anti-Doping Commission may reopen the case on its own initiation.

WADA shall be informed of a decision not to proceed with a case. If WADA so requests, the Anti-Doping Commission shall reopen the case and request the National Federation to instigate disciplinary proceedings in accordance with article 224.

- 185.** Before taking a decision, the Anti-Doping Commission may order additional investigations. National Federations shall be obliged to conduct such investigations as the Anti-Doping Commission may deem appropriate. All *License-Holders* are obliged to assist.

- 186.** Upon receipt of an *A Sample Adverse Analytical Finding*, the Anti-Doping Commission shall conduct a review to determine whether: (a) an applicable Therapeutic Use Exemption has been granted, or (b) there is any apparent departure from these Anti-Doping Rules, the *Procedural Guidelines* or the *International Standards for Testing* or laboratory analysis that undermines the validity of the *Adverse Analytical Finding*.

- 187.** If the initial review under article 186 does not reveal an applicable Therapeutic Use Exemption or departure from these Anti-Doping Rules, the *Procedural Guidelines*, the *International Standard for Testing* or the *International Standard* for laboratory analysis in force at the time of *Testing* or analysis that undermines the validity of the *Adverse Analytical Finding*, the Anti-Doping Commission shall promptly notify the *Rider's* National Federation of: (a) the *Adverse Analytical Finding*; (b) the anti-doping rule violated, or a description of the additional investigation that will be conducted as to whether there is an anti-doping rule violation; (c) the *Rider's* right to promptly request the analysis of the *B Sample* or, failing such request, that the *B Sample* analysis shall be deemed waived; (d) the right of the *Rider* and/or the *Rider's* representative to attend the *B Sample* opening and analysis if such analysis is requested; and (e) the *Rider's* right to request copies of the *A* and *B Sample* laboratory documentation package which includes information as required by the *International Standard* for laboratory analysis.

A copy of the notification may be sent to the *Rider* and/or the *Rider's* club or team.

A copy of the notification is sent to WADA and to the *Rider's* National Anti-Doping Organization.

- 188.** The *Rider's* National Federation shall within 2 (two) working days send a copy of the notification from the Anti-Doping Commission to the *Rider* concerned. It shall also notify the UCI that this copy has been sent.

UCI CYCLING REGULATIONS

- 189.** The notification of the *Rider's* National Federation under article 187 and the notification of the *Rider* under article 188 shall be confirmed by the dispatch of a registered letter with proof of delivery.
- 190.** Any communication by the National Federation will be deemed valid if sent to the most recent address for the *Rider* as notified to the National Federation.

Analysis of B Sample

- 191.** The *Rider* and/or his National Federation and the Anti-Doping Commission shall be entitled to demand the analysis of the B Sample.
- 192.** The request for the analysis of the B Sample shall indicate whether the *Rider* wants not only the opening, but also the analysis of the B Sample to be attended by him or a representative.
- 193.** The request for the analysis of the B Sample shall be made directly to the laboratory by the *Rider's* National Federation, either on its own initiative or at the request of the *Rider*. A copy of the request for the analysis must be sent to the UCI at the same time.
- 194.** To be acceptable, the request for the analysis of the B Sample by the National Federation shall be sent to the laboratory no more than 5 (five) working days after receipt of the registered letter sent to the National Federation of the *Rider* informing it of the A Sample Adverse Analytical Finding.
- 195.** The analysis of the B Sample shall be conducted by the laboratory that conducted the analysis of the A Sample.
- However, if justified by the need to have the B Sample analyzed, the UCI Anti-Doping Commission may decide that the analysis of the B Sample shall be carried out by another laboratory which it shall designate.
- 196.** The analysis of the B Sample may be carried out by 2 (two) laboratories in accordance with article 177. Should the analysis of the A Sample carried out in this fashion have shown that the Adverse Analytical Finding is verifiable in the second laboratory only, the analysis of the B Sample shall be valid if carried out in this laboratory.
- 197.** The opening of the B Sample may be attended by the *Rider*, an expert designated by him or by his National Federation, a representative of the *Rider's* National Federation and a representative of the UCI.
- 198.** The analysis of the B Sample may be attended by the *Rider* or one representative if such request was made when the B Sample analysis was requested. The laboratory may restrict the attendance in order to avoid any disturbance of the analysis.
- 199.** The laboratory, in consultation with the parties involved, sets a date for the analysis of the B Sample in a period of 10 (ten) working days after reception of the request excepted the opposed agreement of the Anti-Doping Commission.

- 200.** The B *Sample* analysis of a blood *Sample* shall take place no later than 3 (three) days after the analysis of the A *Sample*. The Anti-Doping Commission shall inform the *Rider* and/or his National Federation as soon as possible of any A *Sample Adverse Analytical Finding* and of the date set for the B *Sample* analysis by fax or by email. The terms and procedures set above shall not apply for notifying the *Rider*.

The B *Sample* analysis shall be valid, even if the *Rider* did not receive notification in time or was unable to attend or to be represented.

- 201.** No party may claim their inability to attend for the analysis of the B *Sample* on the date set as a reason for invalidating the analysis of the B *Sample*.

- 202.** The *Rider's* National Federation shall be responsible for the costs of the analysis of the B *Sample*.

The *Rider's* National Federation may submit the request for the analysis following payment by the *Rider* of a sum not exceeding CHF 700.

- 203.** A *Rider* may accept the A *Sample* analytical results and waive the B *Sample* analysis. The UCI may nonetheless elect to proceed with the B *Sample* analysis.

- 204.** If the B *Sample* proves negative, the entire test shall be considered negative and the *Rider*, his National Federation, his National Anti-Doping Organization and WADA shall be so informed.

- 205.** If a *Prohibited Substance* or the *Use* of a *Prohibited Method* is identified, the findings shall be reported to the *Rider*, his National Federation, his National Anti-Doping Organization and to WADA.

A copy of the report may be sent to the *Rider's* team or club.

Follow-up investigations

- 206.** The Anti-Doping Commission shall conduct any follow-up investigation as may be required by the *Prohibited List*. Upon completion of such follow-up investigation, the Anti-Doping Commission shall promptly notify the *Rider* regarding the results of the follow-up investigation and whether or not the Anti-Doping Commission asserts that an anti-doping rule was violated.

- 207.** The costs of follow-up investigations are at the expense of the *Rider*. The *Rider* may be requested to advance costs. If the *Rider* refuses to do so, he is presumed to have accepted the analytical results and the case shall proceed accordingly.

Test results management at World Championships

- 208.** During World Championships, the laboratory shall report any *Adverse Analytical Finding* to the UCI official doctor.

If it is not possible for the test results to reach the UCI official doctor before the end of the Championships, they shall be sent to the UCI Anti-Doping Commission.

- 209.** Upon receipt of an *A Sample Adverse Analytical Finding* from a test conducted at the World Championships, the UCI official doctor shall conduct the review described in article 186 and, where applicable, notify the *Rider* or, should this be impossible, his team manager immediately.
- 210.** The UCI official doctor shall without further formalities call for the analysis of the *B Sample*, at which he has the right to be present. He shall inform the *Rider* and the delegation from his National Federation of the place, date and time of the analysis. No postponement of the analysis may be granted.
- 211.** If the *B Sample* analytical result confirms the *A Sample* analytical result, the UCI official doctor shall inform the *Rider*, the president of the commissaires panel, the Anti-Doping Commission and the *Rider's* National Federation.
The notification to the *Rider's* National Federation may be made to the delegation from that Federation attending the Championships.

Results management at stage races and six-days races

- 212.** During a stage race or a six-day race, upon receipt of an *A Sample Adverse Analytical Finding* from a test conducted at that stage race or a six-days race and completion of the review described in article 186, the Anti-Doping Commission shall notify the *Rider* via the president of the commissaires panel.

The president of the commissaires panel shall hear the *Rider's* explanations.

- 213.** The request for the analysis of the *B Sample* shall be submitted in writing to the *Anti-Doping Inspector* within 3 (three) hours of the notification specified in article 212.

The *Rider* shall be issued with a receipt stating the time that the request was submitted.

- 214.** No postponement of the analysis of the *B Sample* may be granted in order to permit attendance by the persons noted in articles 145 and 146 beyond 4 (four) days from the date of the request for the analysis.

- 215.** The *Anti-Doping Inspector* shall submit the *B Sample* analysis report to the president of the commissaires panel.

- 216.** If the *B Sample* analytical result confirms the *A Sample* analytical result, the Anti-Doping Commission shall inform the president of the commissaires panel for the purposes of article 219.

VIII

Chapter PROVISIONAL MEASURES

- 217.** 1. If after the review described in articles 184 to 206 the Anti-Doping Commission asserts that an anti-doping violation under article 15.1 or article 15.2 was committed, the Anti-Doping Commission may ban the *Rider* from participating in *Events* for such time that the violation, in the opinion of the Anti-Doping Commission, is likely to affect the *Rider's* results.
2. Before the ban goes into effect or on a timely basis thereafter, the *Rider* shall be given an opportunity to be heard in either written or oral form. The President of the Anti-Doping Commission may appoint a member of the Anti-Doping Commission, including himself, or an *Anti-Doping Inspector* to hear the *Rider*.
3. The decision shall be taken by the member of the Anti-Doping Commission who has heard the *Rider* or, if the *Rider* was heard by an *Anti-Doping Inspector*, by the President of the Anti-Doping Commission having received the account of the *Anti-Doping Inspector*.

- 218.** If after the initial review described in article 186 and at the eve or during a particular *Event*, the Anti-Doping Commission makes an assertion that an anti-doping violation may have been committed under articles 15.1 or 15.2 and determines that the asserted anti-doping violation, that occurred prior to that *Event*, may affect the *Rider's* results at the *Event*, the Anti-Doping Commission may request that the *Rider* is banned from the *Event*.

The request shall be made to the president of the commissaires panel. The president of the commissaires panel shall summon the *Rider* to be heard and decide whether the *Rider* shall be banned from the *Event*.

- 219.** If, during an *Event* and where applicable after the review described in article 186 the Anti-Doping Commission or, at World Championships, the official doctor asserts that an anti-doping violation has been committed during the same *Event*, the Anti-Doping Commission or the official doctor will inform the president of the commissaires panel for the *Event*. The president of the commissaires panel shall summon the *License-Holder* concerned to be heard. The president of the commissaires panel may *Disqualify* the *Rider* or ban the *License-Holder* from the *Event* subject to the due opinion of the President or another member of the Anti-Doping Commission.

If a *Rider* is *Disqualified* for an asserted violation under articles 15.1 or 15.2 that occurred during a team race, the *Rider's* team shall be relegated to the last place of the race. In stage races on the road and subject to the application of article 279 after the decision of the hearing body, the team will be given its actual time.

- 220.** In case of a recorded warning or a missed test in a period of 45 (forty-five) days before the start of a Major Tour, the *Rider* is not allowed to participate in that Tour.

- 221.** The provisional measures under articles 217, 218 and 219 may be combined.

Such provisional measures may also be imposed on *Rider's Support Personnel* against whom an anti-doping violation is asserted for any period prior to the decision of the hearing body.

- 222.** The provisional measures stipulated above are intended to preserve fair competition. They shall not prejudice the decision whether an anti-doping violation has occurred and shall not give rise to any claim in the event that the *License-Holder* is acquitted.
- 223.** Provisional measures regarding a *License-Holder* who has been referred to his National Federation according to article 183, shall be governed by the rules of the National Federation. Under all circumstances such *License-Holder* shall be *Disqualified* from participation in an *International Event* prior to the decision of the hearing body.

IX

Chapter RIGHT TO A FAIR HEARING

- 224.** When, following the results management process described in chapter VII, the Anti-Doping Commission makes an assertion that these Anti-Doping Rules have been violated, it shall notify the *License-Holder's* National Federation and request it to instigate disciplinary proceedings. It shall also send a copy of the test analysis report and/or other documentation. A copy of the statement may be sent to the *License-Holder* and/or the *License-Holder's* club or team.

A copy of the statement is sent to WADA and to the *License-Holder's* National Anti-Doping Organization.

***License-Holder* called before his National Federation**

- 225.** The *License-Holder's* National Federation shall call the *License-Holder* before it to hear his grounds and explanations.

This summons must be sent within 2 (two) working days of the receipt of the statement under Article 224.

- 226.** The summons shall be sent by registered letter. It shall indicate the nature of the case against the *License-Holder*. The summons must be accompanied by a copy of the test analysis reports and documents received by the Federation from the Anti-Doping Commission. If these enclosures are missing, the *License-Holder* must notify the National Federation without delay.

- 227.** The summons must be sent at least 10 (ten) days before the hearing to which the *License-Holder* has been called. A copy of the summons shall be sent to the UCI at the same time.

The summons shall indicate the date, time and venue for the hearing.

228. A single postponement to the hearing may be granted of not more than 8 (eight) days, except where the party concerned establishes a case of force majeure.

229. The *License-Holder* may forgo the hearing in which event the case will be conducted in writing.

Rights of the defense

230. The *License-Holder* shall be heard and the case investigated by the competent hearing body of the *License-Holder's* National Federation in accordance with the regulations of the *License-Holder's* National Federation whilst taking account of the following articles:

231. The hearing body shall be fair and impartial.

232. At the request of one of the parties to the case or at their own request the following shall also be heard: the organiser's National Federation, the laboratory which carried out the analysis, the *Anti-Doping Inspector*, the *Medical Inspector*, witnesses and expert witnesses.

The interested party shall be responsible for calling these persons to the proceedings and for their costs. It shall at the same time notify the other parties and the competent body.

233. The UCI may give its opinion in each case and demand that a sanction be imposed, either in writing or at the hearing.

It may call for a copy of the documentation of the case in full, including the proceedings of the hearing and the documents submitted by the parties.

234. The parties must provide each other with all the statements and documents which they intend to submit at the earliest opportunity. They shall also send them to the UCI at the same time.

235. The *License-Holder* has the right to see the contents of the case files. Each party may obtain a copy at its own expense.

Furthermore the case files may be consulted during the hearing.

236. The hearing shall be public unless the *License-Holder* requests otherwise.

The president of the hearing body may also as of right prohibit public access to the room during all or part of the hearing in the interest of public order or when the protection of privacy or medical secrecy justifies it.

237. Each party shall have the right to be represented by a qualified lawyer or by a representative on presentation of authorization in writing. The parties may be aided by any other person of their choice.

- 238.** Each party and any witnesses and expert witnesses called shall be heard subject to the hearing body's discretion to accept testimony by telephone or written submission. The *License-Holder* shall have the right to speak last.
- 239.** In the event that a party who has been convened should fail to appear, the case will be heard in that party's absence. The decision shall be deemed to have been taken after due hearing of the parties.
- 240.** If the hearing body determines that the *License-Holder* has insufficient knowledge of the language of the proceedings, the *License-Holder* has the right to an interpreter at the hearing. The hearing body will determine the identity and responsibility for the cost of the interpreter.
- 241.** Each party is responsible for the costs of interpreters for its witnesses and experts.

Decision

- 242.** The decision of the hearing body shall note the identities of the parties called or heard and shall contain a brief summary of the procedure.

It shall bear the names of the persons who took the decision and must be signed by them.

- 243.** The decision shall be dated and reasoned.

It shall, where appropriate, indicate the *Prohibited Substances* or *Prohibited Methods* for which the *Rider* has been declared positive.

It shall indicate the sanctions imposed on the *License-Holder*.

Costs

- 244.** Subject to article 245 and in the absence of a specifically justified decision, each party shall bear the costs which it incurs.

- 245.** If the *License-Holder* is found guilty of an anti-doping violation, he shall bear:
1. The cost of the proceedings as determined by the hearing body.
 2. The cost of the result management by the Anti-Doping Commission; the amount of this cost shall be CHF 1000, unless a higher amount is claimed by the UCI and determined by the hearing body.
 3. The cost of the B Sample analysis, where applicable. The National Federation shall be jointly and severally liable for its payment to the UCI.
- The *License-Holder* shall owe the costs under 2) and 3) also if they were not awarded in the decision.

- 246.** Should the *License-Holder* be acquitted the party nominated in the decision shall be liable for the costs under article 245.2.

Notification of the decision

- 247.** One full copy of the decision, signed at least by the president of the hearing body, shall be sent to the *License-Holder* and the UCI. These copies shall be sent by registered post with proof of receipt within 3 (three) working days of the decision. The UCI shall send the text of the decision to WADA and to the *License-Holder's National Anti-Doping Organization*.

Exclusion of an appeal at national level

- 248.** The decision by the hearing body of a *License-Holder's National Federation* shall not be subject to an appeal before another body (appeals board, tribunal, etc.) at National Federation level.

If such an appeal is entered, it must be declared inadmissible. Any other decision is void as of right. However, the UCI may ask the Court of Arbitration for Sport (CAS) to pronounce nullity where appropriate upon supplementary application in an appeal procedure against the decision of the competent body. This application may be made at any time during the procedure before the CAS.

Duration of the proceedings

- 249.** The National Federation shall keep the UCI fully informed as to the status of the case.
- 250.** The proceedings before the hearing body of the *License-Holder's National Federation* must be completed within 1 (one) month from the time limit set for the dispatch of the summons.

The National Federation shall be penalized by the disciplinary commission, incurring a fine of CHF 5000 for each week's delay without prejudice to the obligation to complete proceedings as fast as possible.

- 251.** If the completion of the hearing is delayed beyond three months, the UCI may elect to bring the case directly to a single arbitrator from the Court of Arbitration for Sport (CAS), acting as a first instance tribunal. The case shall be handled in accordance with the Court of Arbitration for Sport appeal procedure without reference to any time limit for appeal. The *License-Holder's National Federation* shall be summoned to participate in the proceedings and shall bear all costs resulting for all parties from bringing the proceedings from the National Federation to the CAS.

- 252.** The *License-Holder* may forego a hearing by acknowledging the violation of these Anti-Doping Rules and accepting *Disqualification*, *Ineligibility* and costs consistent with these Anti-Doping Rules as proposed or accepted by the Anti-Doping Commission.

- 253.** If any new fact is revealed of a nature which might alter the decision issued by the hearing body of the *License-Holder's National Federation* after the date of pronouncement, the interested party may request that the case be reopened before the National Federation, unless it is possible to raise the new issue in existing proceedings before the CAS.

The new evidence must predate the decision of the hearing body, and the party submitting it must establish that it could not have known about it prior to the hearing where the decision was issued.

The request to reopen the case must be made within one month of the party's becoming aware of the evidence in question or it shall be debarred. The burden of proof regarding this date shall lie with the party submitting the new evidence.

- 254.** Articles 248, 250 and 251 shall not apply to the *License-Holder* that was referred to his National Federation according to article 183.

X

Chapter SANCTIONS AND CONSEQUENCES

- 255.** These Anti-Doping Rules concerning sanctions and consequences shall be construed and implemented in compliance with human rights and general principles of law, among which proportionality and individual case management.

Automatic Disqualification of individual results

- 256.** A violation of these Anti-Doping Rules in connection with an *In-Competition* test automatically leads to *Disqualification* of the individual result obtained in that *Competition*.

Disqualification of Results in Event during which an Anti-Doping Rule Violation occurs

- 257.** Except as provided in articles 258 and 259, an anti-doping rule violation occurring during or in connection with an *Event* leads to *Disqualification* of the *Rider's* individual results obtained in that *Event* according to the following rules:

1. If the violation is a violation of
 - a) article 15.5 (*Tampering or Attempting to tamper*), or
 - b) article 15.6 (*Possession*), or
 - c) article 15.7 (*Trafficking*), or
 - d) article 15.8 (*Administration, Attempted administration or any type of complicity*),all of the *Rider's* individual results are disqualified.
2. If the violation involves
 - a) the presence, *Use* or *Attempted Use* of a *Prohibited Substance* or a *Prohibited Method* (articles 15.1 and 15.2), other than a *Specified Substance*; or
 - b) evading *Sample* collection or refusing to submit to *Sample* collection (article 15.3); or
 - c) failing to submit to *Sample* collection (article 15.3), except when the *Rider* establishes that he bears *No Significant Fault or Negligence*;

all of the *Rider's* results are disqualified, except for the results obtained (i) in *Competitions* prior to the *Competition* in connection with which the violation occurred and for which the *Rider* was tested with a negative result, and (ii) in *Competitions* prior to the *Competition(s)* under point 1.

3. If the violation involves the presence, *Use* or *Attempted Use* of a *Specified Substance*, all of the *Rider's* results obtained in *Competitions* posterior to the *Competition* in connection with which the violation occurred are disqualified, except for those results which were not likely to have been affected by the violation.
 4. If the violation is a failure to submit to *Sample* collection and if the *Rider* establishes that he bears *No Significant Fault or Negligence*, the *Rider's* results obtained in other *Competitions* shall not be disqualified.
- 258.** If the anti-doping violation involves the presence, *Use* or *Attempted Use* of a *Prohibited Substance* or a *Prohibited Method* (article 15.1 and 15.2) and the *Rider* establishes that he bears *No Fault or Negligence*, his individual results in the other *Competitions* shall not be disqualified except to the extent that they were likely to have been affected by the *Rider's* anti-doping violation.
- 259.** 1. If the *Event* is a stage race, an anti-doping violation committed in connection with any stage, entails *Disqualification* from the *Event*, except when (i) the anti-doping violation involves the presence, *Use* or *Attempted Use* of a *Prohibited Substance* or a *Prohibited Method*, (ii) the *Rider* establishes that he bears *No Fault or Negligence* and (iii) his results in no other stage were likely to have been influenced by the *Rider's* anti-doping violation.
2. If the anti-doping violation committed in a stage race involves the presence, *Use* or *Attempted Use* of a *Specified Substance* and only a warning and reprimand are imposed, *Disqualification* from the *Event* is optional.
- If the *Rider* is not *Disqualified* from the *Event*, 1% (one percent) of the time recorded by the *Rider* during the stage on which he tested positive shall be added to the final time on the individual classification. The number of points scored during that same stage shall be deducted from the final classification. Any prize won in connection with the stage in which the anti-doping violation occurred shall be forfeited.
- 260.** In those cases that are not considered under articles 257 to 259, the *Disqualification* of the *Rider's* individual results obtained on the *Event* is optional.

Imposition of Ineligibility for Prohibited Substances and Prohibited Methods

- 261.** Except for the specified substances identified in article 262, the period of *Ineligibility* imposed for a violation of article 15.1 (presence of *Prohibited Substance* or its *Metabolites* or *Markers*), article 15.2 (*Use* or *Attempted Use* of *Prohibited Substance* or *Prohibited Method*) and article 15.6 (*Possession of Prohibited Substances and Methods*) shall be:

First violation: 2 (two) years' *Ineligibility*

Second violation: Lifetime *Ineligibility*

However, the *License-Holder* shall have the opportunity in each case, before a period of *Ineligibility* is imposed, to establish the basis for eliminating or reducing this sanction as provided in articles 264 and 265.

Specified Substances

262. Where a *Rider* can establish that the Use of a *Specified Substance* was not intended to enhance sport performance, the period of *Ineligibility* found in article 261 shall be replaced with the following:

First violation: At a minimum, a warning and reprimand and no period of *Ineligibility* from future *Events*, and at a maximum, 1 (one) year's *Ineligibility*.

Second violation: 2 (two) years' *Ineligibility*

Third violation: Lifetime *Ineligibility*

However, the *License-Holder* shall have the opportunity in each case, before a period of *Ineligibility* is imposed, to establish the basis for eliminating or reducing (in the case of a second or third violation) this sanction as provided in articles 264 and 265.

Ineligibility for other Anti-Doping Rule Violations

263. The period of *Ineligibility* for other violations of these Anti-Doping Rules shall be:

1. For violations of article 15.3 (evading *Sample* collection, refusing or failing to submit to *Sample* collection) or article 15.5 (*Tampering with Doping Control or Attempting*), the *Ineligibility* periods set forth in article 261 shall apply.
2. For violations of article 15.7 (*Trafficking*) or article 15.8 (administration of *Prohibited Substance* or *Prohibited Method*), the period of *Ineligibility* imposed shall be a minimum of 4 (four) years up to lifetime *Ineligibility*. An anti-doping rule violation involving a *Minor* shall be considered a particularly serious violation, and, if committed by *Rider Support Personnel* for violations other than specified substances referenced in article 262, shall result in lifetime *Ineligibility* for such *Rider Support Personnel*. In addition, violations of such articles which also violate non-sporting laws and regulations, may be reported to the competent administrative, professional or judicial authorities.
3. For violations of article 15.4, as defined in article 86, (*Whereabouts Violations or Missed Tests*), the period of *Ineligibility* shall be:

First violation: 3 (three) months to 1 (one) year *Ineligibility*.

Second and subsequent violations: 1 (one) year to 2 (two) years' *Ineligibility*.

Elimination or Reduction of Period of *Ineligibility*

- 264.** If the *Rider* establishes in an individual case involving an anti-doping rule violation under article 15.1 (presence of *Prohibited Substance* or its *Metabolites* or *Markers*) or *Use of a Prohibited Substance* or *Prohibited Method* under article 15.2) or an anti-doping violation under article 15.6 (*Possession of Prohibited Substances* or *Methods*) that he bears *No Fault or Negligence* for the violation, the otherwise applicable period of *Ineligibility* shall be eliminated. When a *Prohibited Substance* or its *Markers* or *Metabolites* is detected in a *Rider's Specimen* in violation of article 15.1 (presence of a *Prohibited Substance*), the *Rider* must also establish how the *Prohibited Substance* entered his system in order to have the period of *Ineligibility* eliminated. In the event this article is applied and the period of *Ineligibility* otherwise applicable is eliminated, the anti-doping rule violation shall not be considered a violation for the limited purpose of determining the period of *Ineligibility* for multiple violations under articles 261, 262 and 269-271.
- 265.** This article 265 applies to anti-doping rule violations involving article 15.1 (presence of a *Prohibited Substance* or its *Metabolites* or *Markers*), *Use of a Prohibited Substance* or *Prohibited Method* under article 15.2, failing to submit to *Sample* collection under article 15.3, *Possession of Prohibited Substances* or *Methods* under article 15.6 or administration of a *Prohibited Substance* or *Prohibited Method* under article 15.8. If a *License-Holder* establishes in an individual case involving such violations that he bears *No Significant Fault or Negligence*, then the period of *Ineligibility* may be reduced, but the reduced period of *Ineligibility* may not be less than one-half of the minimum period of *Ineligibility* otherwise applicable. If the otherwise applicable period of *Ineligibility* is a lifetime, the reduced period under this section may be no less than 8 (eight) years. When a *Prohibited Substance* or its *Markers* or *Metabolites* is detected in a *Rider's Specimen* in violation of article 15.1 (presence of *Prohibited Substance*), the *Rider* must also establish how the *Prohibited Substance* entered his system in order to have the period of *Ineligibility* reduced.
- 266.** The Hearing Panel may also reduce the period of *Ineligibility* in an individual case where the *License-Holder* has provided substantial assistance which results in discovering or establishing an anti-doping rule violation by another *Person* involving *Possession* under article 15.6.2 (*Possession by Rider Support Personnel*), article 15.7 (*Trafficking*), or article 15.8 (administration to a *Rider*). The reduced period of *Ineligibility* may not, however, be less, in principle, than one-half of the minimum period of *Ineligibility* otherwise applicable. If the otherwise applicable period of *Ineligibility* is a lifetime, the reduced period under this Article may be no less than 8 (eight) years.
- 267.** If the sanction imposed exceeds the maximum set under these Anti-Doping Rules, it shall automatically be reduced to this maximum, without prejudice to the right of appeal of the person sanctioned.

Declaration or admission of doping

- 268.** A *License-Holder* who declares or admits to having committed an anti-doping violation shall be considered as having committed that violation on the day of the declaration or admission, unless the facts admitted or declared can be tied to a specific instance, in which case the sanctions in force at the time of the facts shall be applied.

Rules for Certain Potential Multiple Violations

- 269.** For purposes of imposing sanctions under articles 261, 262 and 263, a second anti-doping rule violation may be considered for purposes of imposing sanctions only if it is established that the *License-Holder* committed the second anti-doping rule violation after he received notice, or after a reasonable attempt was made to give notice of the first anti-doping rule violation; if not, the violations shall be considered as one single first violation, and the sanction imposed shall be based on the violation that carries the more severe sanction.
- 270.** Where a *Rider*, based on the same *Testing*, is found to have committed an anti-doping rule violation involving both a *Specified Substance* under article 262 and another *Prohibited Substance* or *Prohibited Method*, the *Rider* shall be considered to have committed a single anti-doping rule violation, but the sanction imposed shall be based on the *Prohibited Substance* or *Prohibited Method* that carries the most severe sanction.
- 271.** Where a *Rider* is found to have committed 2 (two) separate anti-doping rule violations, one involving a *Specified Substance* governed by the sanctions set forth in article 262 (*Specified Substances*) and the other involving a *Prohibited Substance* or *Prohibited Method* governed by the sanctions in article 261 or a violation governed by the sanctions in article 263.1, the period of *Ineligibility* imposed for the second violation shall be at a minimum 2 (two) years' *Ineligibility* and at a maximum 3 (three) years' *Ineligibility*. Any *Rider* found to have committed a third anti-doping rule violation involving any combination of *Specified Substances* under article 262 and any other anti-doping rule violation under article 261 or 263.1 shall receive a sanction of lifetime *Ineligibility*.
- 272.** If an anti-doping violation has been sanctioned without consideration having been given to a former condemnation for another violation, the case may be reopened at the request of the Anti-Doping Commission.
- 273.** Should an anti-doping violation be discovered that has occurred prior to another violation that has already been sanctioned, the former shall be sanctioned as a second or subsequent violation.

Disqualification of Results in Competitions Subsequent to anti-doping violation

- 274.** In addition to the automatic *Disqualification* of the results in the *Competition* pursuant to article 256, all other competitive results obtained from the date a positive *Sample* was collected (whether *In-Competition* or *Out-of-Competition*), or other doping violation occurred, through the commencement of any *Ineligibility* period, shall, unless fairness requires otherwise, be *Disqualified*.

Comment: it may be considered as unfair to disqualify the results which were not likely to have been affected by the Rider's anti-doping rule violation.

Commencement of Ineligibility Period

- 275.** The period of *Ineligibility* shall start on the date of the hearing decision providing for *Ineligibility* or, if the hearing is waived, on the date *Ineligibility* is accepted or otherwise imposed. Any period during which provisional measures pursuant to articles 217 through 223 were imposed or voluntarily accepted and any period for which subsequent *Competition* results have been *Disqualified* under article 274 shall be credited against the total period of *Ineligibility* to be served. Where required by fairness, such as delays in the hearing process or other aspects of Doping Control not attributable to the *License-Holder*, the hearing body imposing the sanction may start the period of *Ineligibility* at an earlier date commencing as early as the date of the anti-doping violation.

Reinstatement Testing

- 276.** As a condition to regaining eligibility at the end of a specified period of *Ineligibility*, a *Rider* must, during any period of provisional measures or *Ineligibility*, make himself available for *Out-of-Competition Testing* by the UCI and any other *Anti-Doping Organization* having *Testing* jurisdiction under the *Code*, and must provide current and accurate whereabouts information as provided in article 76.
- 277.** If a *Rider* subject to a period of *Ineligibility* retires from sport and is removed from UCI's *Registered Testing Pool* and later seeks reinstatement, the *Rider* shall not be eligible for reinstatement until he has notified the UCI and his National Federation and has been subject to *Out-of-Competition Testing* for a period of time equal to the longer of the period set forth in article 77 or the period of *Ineligibility* remaining as of the date the *Rider* had retired.

Consequences to teams

- 278.** Except as provided in article 279, if a *Rider* is found to have committed an anti-doping violation in connection with a team *Competition* in which he participated as a member of a team, the team shall be *disqualified* from that *Competition*.

UCI CYCLING REGULATIONS

If such *Rider* is *disqualified* from other *Competitions* of the same *Event* under articles 257.2a or 3 or article 258, any team, whether composed differently or not, of which such *Rider* was a member, shall be *disqualified* from the same *Competitions* as the *Rider*.

- 279.** In the case of a team stage during a stage race, the team shall be relegated to the last place on the stage with its real time and with a 10 (ten) minutes penalty on the general classification of teams. If more than one *Rider* on the team is found to have committed an anti-doping violation during the same team stage, the team is *disqualified* from the stage race.

XI

Chapter APPEAL TO THE CAS

- 280.** The following decisions may be appealed to the Court of Arbitration for Sport:
- a) the decisions of the hearing body of the National Federation under article 242;
 - b) a decision that a *Rider* shall be banned from participating in *Events* under article 217 if the ban is for more than 1 (one) month;
 - c) the decisions concerning Therapeutic Use Exemptions as specified under articles 67, 68, 70 and 72.
 - d) the final decision at the level of the National Federation regarding a *License-Holder* that was referred to his National Federation according to article 183.

No other form of appeal shall be permitted.

- 281.** In cases under article 280 a), the following parties shall have the right to appeal to the CAS:
- a) the *License-Holder* who is the subject of the decision being appealed;
 - b) the other party to the case in which the decision was rendered;
 - c) the UCI;
 - d) the International Olympic Committee or International Paralympic Committee, where the decision may have an effect in relation to the Olympic Games or Paralympic Games, including decisions affecting eligibility for the Olympic Games or Paralympic Games;
 - e) WADA.

- 282.** The appeal of the UCI shall be made against the *License-Holder* and against the National Federation that made the contested decision and/or the body that acted on his behalf. The National Federation or body concerned shall be liable for costs if the hearing body which made the decision against which the appeal has been made has applied the regulations incorrectly.

- 283.** An appeal by the *License-Holder* shall be made against his National Federation.

The National Federation must immediately send the UCI a copy of the statement of appeal and of any submissions or briefs made before the CAS.

The UCI shall have the right to participate in the proceedings before the CAS and demand that a sanction is imposed or increased.

- 284.** The statement of appeal by the *License-Holder* or the other party to the case must be submitted to the CAS within 1 (one) month of his receiving the full decision as specified in article 247. Failure to respect this time limit shall result in the appeal being disbarred.
- 285.** The statement of appeal by the UCI, the International Olympic Committee, the International Paralympic Committee or WADA must be submitted to the CAS within 1 (one) month of receipt of the full case file from the hearing body of the National Federation. Failure to respect this time limit shall result in the appeal being disbarred. Should the appellant not request the file within 15 (fifteen) days of receiving the full decision as specified in article 247, the time limit for appeals shall be 1 (one) month from the reception of that decision.
- 286.** If the respondent makes a counter-appeal, the appellant has the right to respond within 1 (one) month of receiving the respondent's reply, except where extended by the CAS. If the respondent is the *License-Holder*, he shall have the right to submit an additional statement within 15 (fifteen) days of receiving the appellant's reply, unless the time limit is extended by the CAS.
- 287.** In cases under article 280 b), the *Rider* only shall have the right to appeal to the CAS.
- The appeal shall be made against the UCI.
- The time to file the appeal to the CAS shall be 8 (eight) days from receipt of the decision by the *Rider* or his National Federation or his club or team.
- 288.** An appeal to the CAS shall not suspend the execution of the contested decision, without prejudice to the right to apply to the CAS for it to be suspended.
- 289.** The CAS shall have full power to review the facts and the law. The CAS may increase the sanctions that were imposed on the appellant in the contested decision.
- 290.** The CAS shall decide the dispute according to these Anti-Doping Rules and the rules of law chosen by the parties or, in the absence of such a choice, according to Swiss law.
- 291.** The decision of the CAS shall be final and binding on the parties to the case and to all *License-Holders* and National Federations. It shall not be subject to appeal.

XII

Chapter CONFIDENTIALITY AND PUBLIC DISCLOSURE

Duty of confidentiality

- 292.** Persons carrying out a task in *Doping Control* are required to observe strict confidentiality regarding any information concerning individual cases which is not required to be reported under these Anti-Doping Rules.

UCI CYCLING REGULATIONS

Such breaches of confidentiality shall be penalized by a fine of between CHF 1000 and CHF 10 000 as decided by the UCI Disciplinary Commission, which may also suspend the person in question from specified tasks for such time as it shall determine.

Public disclosure

293. Public disclosure shall be made by the Anti-Doping Commission or the National Federation as described in article 295.

294. *License-Holders* who are asserted to have committed a violation of these Anti-Doping Rules shall in principle not be publicly identified until it has been determined in a decision in accordance with articles 230 to 243 that an anti-doping violation has occurred.

However, the Anti-Doping Commission and the National Federation of the *License-Holder* who is asserted to have committed a violation of these Anti-Doping Rules may make public statements and identifications they deem appropriate under the circumstances, but not earlier than the moment of sending the notification referred to in article 224.

295. Once a violation of these Anti-Doping Rules has been established in a decision referred to in article 243, it shall be publicly reported as follows:

- if the UCI decides to appeal to the CAS, the UCI will report the violation, the decision and its decision to appeal no later than the expiration of the time limit for the appeal;
- if the UCI decides not to appeal to the CAS, it will report the violation and the decision no later than 10 (ten) days after the expiration of the time limit for the appeal.
- if the *License-Holder* or WADA appeals to the CAS, the UCI will report the violation, the decision and the appeal within 10 (ten) days after the appeal was notified to the UCI.

Publication

296. The definitive sanctions and the name of the person penalized shall be published in the UCI Official News Bulletin and/or in the official bulletin of the National Federation of the person penalized.

Register

297. The Anti-Doping Commission shall maintain a register of the penalties applied. This shall list the name of the *License-Holder*, his National Federation, his category (elite or other), the name and date of the *Event*, the penalties imposed, the date of the decision regarding the penalties and the body which imposed them.

XIII

Chapter FINAL PROVISIONS

Third Sample

- 298.** The UCI shall have the right to demand that a third *Sample* be taken at a *Sample* taking session. The Anti-Doping Commission shall issue instructions to his end to the *Anti-Doping Inspector*. The *Sample* taking procedures shall be applied *mutatis mutandis*. The taking of a third *Sample* shall be recorded.

Where appropriate, the further analysis of such *Samples* shall give rise to action for an anti-doping violation and sanctions.

Violations described under articles 15.3 and 15.5 shall apply regarding the third *Sample*.

Medication

- 299.** In *Events* designated by the Anti-Doping Commission, team or club doctors will be obliged to list all medicines taken by each *Rider* and their dosages and any medical treatment that they may have undergone during the preceding 72 (seventy-two) hours. Failure to do so shall make the team ineligible to start the race.

National Federations

- 300.** When a National Federation receives from third parties information concerning a possible anti-doping violation, it shall immediately inform the Anti-Doping Commission of the UCI.
- 301.** All National Federations shall include in their regulations the rules necessary to effectively implement these Anti-Doping Rules.
- 302.** For the purpose of these Anti-Doping Rules, the organizer's National Federation shall take on the role of the *License-Holder's* National Federation as regards *License-Holders* who have obtained their license directly from the UCI.
- 303.** Without prejudice to article 13 of the Constitution, National Federations shall be obligated to reimburse the UCI for all costs related to a doping case in which the National Federation was not cooperative or did not comply with these Anti-Doping Rules.

UCI CYCLING REGULATIONS

Non-License-Holders

- 304.** 1. If a breach of these Anti-Doping Rules is committed by a non-*License-Holder*, the Anti-Doping Commission and/or any National Federation involved shall take whatever steps are necessary to take proceedings before the competent bodies against the person in question.
2. Right to a fair hearing having granted, the Anti-Doping Commission may ban this person from attending a cycling *Event*. It may also ban any National Federation, club or trade team from making use of services offered by this person, with breaches of such a ban being subject to a fine of between CHF 1000 and CHF 10000 as determined by the Disciplinary Commission. These measures and sanctions may be taken independently of the procedure noted under paragraph 1.

Independent Observers

- 305.** Organizers shall provide access to Independent Observers as directed by the UCI.

Recognition of decisions by other organizations

- 306.** 1. Subject to the right to appeal provided in chapter XI, the *Testing*, therapeutic use exemptions and hearing results or other final adjudications of any *Signatory* to the *Code* which are consistent with the *Code* and are within the *Signatory's* authority, shall be recognized and respected by the UCI and the National Federations.
2. The UCI may recognize the same actions of other bodies which have not accepted the *Code* if the applicable rules of those bodies are otherwise consistent with the *Code*. The National Federations shall respect such actions when recognized by the UCI.
3. When agreed or otherwise decided between the UCI and the competent authorities, the UCI and the National Federations may administrate results management, hearings and appeals for the application of anti-doping legislation.

Statute of limitations

- 307.** No action may be commenced under these Anti-Doping Rules against a *License-Holder* for a violation of an anti-doping rule contained in these Anti-Doping Rules unless such action is commenced within 8 (eight) years from the date the violation occurred.

Any request for investigation or for disciplinary action and any act of investigation or disciplinary action in relation with the violation shall be considered as commencement of the action for the purpose of this article.

Interpretation of Anti-Doping Rules

- 308.** 1. The headings used for the various parts and articles of these Anti-Doping Rules are for convenience only and shall not be deemed part of the substance of these Anti-Doping Rules or to affect in any way the language of the provisions to which they refer.
2. The Introduction and the Appendix 1 "Definitions" shall be considered integral parts of these Anti-Doping Rules.
3. Notice to a *License-Holder* may be accomplished by delivery of the notice to his National Federation or as provided by these Anti-Doping Rules. The National Federation shall be responsible for making immediate contact with the *License-Holder*.
4. These Anti-Doping Rules shall not apply retrospectively to matters pending before the date these Anti-Doping Rules came into effect.

Entry into force

- 309.** This version of the Anti-Doping Rules of the UCI shall come into force on 13 August 2004, except:
- 1) Until 31 December 2004, the therapeutic use exemption rules of the Anti-Doping Examination rules in force on 12 August 2003, continue to be in force and the exemption remain valid under these Anti-Doping Rules.
- 2) Article 15.4 shall come into force on 1 January 2005.
- 3) Until the introduction of the Procedural Guidelines of the Anti-Doping Commission, *Doping Control* shall be deemed in compliance with these Anti-Doping Rules when in compliance with the Anti-Doping Examination Regulations in force on 12 August 2004.
- 4) Until 31 December 2004, results management and disciplinary proceedings (hearings and appeals), shall be deemed in compliance with these Anti-Doping Rules when in compliance with the Anti-Doping Examination Regulations in force on 12 August 2004.
- 5) The Anti-Doping Examination Regulations in force on 12 August 2004 remain in force until 31 December 2004 for *National Events*.
- 6) Any period of suspension imposed under the Anti-Doping Examination Regulations in force until 12 August 2004 ends on 12 August 2004 if at that moment it exceeds the maximum set under these Anti-Doping Rules, and is reduced to this maximum otherwise.
- 310.** Amendments to these Anti-Doping Rules shall come into force on the date of their publication in the Official News Bulletin unless this publication specifies a different date for entry into force.

(Appendix 1)

DEFINITIONS

Adverse Analytical Finding:

A report from a laboratory or other approved *Testing* entity that identifies in a *Specimen* the presence of a *Prohibited Substance* or its *Metabolites* or *Markers* (including elevated quantities of endogenous substances) or evidence of the *Use* of a *Prohibited Method*.

Anti-Doping Inspector:

Doping control officer with overall responsibility for the on site management of the *Testing* as described in these Anti-Doping Rules and in the *Procedural Guidelines*.

Anti-Doping Organization:

A *Signatory* of the Code that is responsible for adopting rules for initiating, implementing or enforcing any part of the *Doping Control* process. This includes, for example, the International Olympic Committee, the International Paralympic Committee, other *Major Event Organizations* that conduct *Testing* at their *Events*, WADA, International Federations, and *National Anti-Doping Organizations*.

Attempt:

Purposely engaging in conduct that constitutes a substantial step in a course of conduct planned to culminate in the commission of an anti-doping rule violation. Provided, however, there shall be no anti-doping rule violation based solely on an *Attempt* to commit a violation if the *Person* renounces the attempt prior to it being discovered by a third party not involved in the *Attempt*.

Code:

The World Anti-Doping Code. The Code is available on WADA's website at www.wada-ama.org or via UCI.

Competition:

A single *Race* organized separately (for example: a one day road race, each of the time trial and road race at the road World Championships) or a series of *Races* forming an organizational unit and producing a final winner and/or general classification (for example: a road race, a track sprint race tournament, a cyclo-ball tournament) (Note: a World Cup series is not an *Event* or *Competition*).

Disqualification:

See article 12.1.022 of the UCI Cycling Regulations.

Doping Control:

The process including test distribution planning, *Sample* collection and handling, laboratory analysis, results management, hearings and appeals.

Event:

A single *Competition* organized separately (for example: a one day road race, a stage race) or a series of *Competitions* conducted together as a single organization (for example: road World Championships, track World Championships, a track World Cup event); a reference to *Event* includes reference to *Competition* and *Race*, unless the context indicates otherwise.

In-Competition:

In-Competition refers to the period that starts one day before or, in the case of a major tour, three days before the day of the start of an *Event* and finishing at midnight of the day on which the *Event* finishes.

However, regarding the *Presence or Use* of a prohibited stimulant as defined in the *Prohibited List*, *In-Competition* refers to the period starting 8 (eight) hours before the start of a *Race* in which the *Rider* is competing or for which he has been confirmed as a starter and finishing at the end of the *Post-Competition Testing* session that is organized following the *Race*.

Independent Observers Program:

A team of observers, under the supervision of WADA, who observe the *Doping Control* process at certain *Events* and report on observations. If WADA is testing *In-Competition* at an *Event*, the observers shall be supervised by an independent organization.

Individual Testing:

Testing on *Riders* that is organized separately, as opposed to *Post-Competition Testing* sessions following a *Race* or *Competition*. *Individual Testing* takes place *In-Competition* (on *Riders* who participate in the *Competition* or were confirmed as starters, at any time other than during the *Post-Competition Testing* session) or *Out-of-Competition*.

Ineligibility:

Under these Anti-Doping Rules, *Ineligibility* is defined as a suspension as described in article 12.1.033 of the UCI Cycling Regulations.

Ineligibility also means that the *License-Holder* is barred, for the period of *Ineligibility*, from participating in any *Competition* or other activity organized or authorized by any *Signatory* or *Signatory's* member organization, and from any funding as provided in article 10.9 of the Code.

International Event / Competition / Race:

An *Event*, *Competition*, *Race* of the international calendar of the UCI.

International Standards:

Standards adopted by WADA in support of the Code. Compliance with the *International Standards* (as opposed to other alternative standards, practice or procedure) shall be sufficient to conclude that the procedures addressed by the *International Standards* were performed properly.

License-Holder:

- 1) A Person who is holder of a license or who has applied for a license under the UCI Cycling Regulations;
- 2) Any Person who, without being a holder of a license, participates in a cycling *Event* in any capacity whatsoever, including, without limitation, as a coach, trainer, manager, team director, team staff, agent, official, medical or para-medical personnel;
- 3) Any Person who, without being a holder of a license, participates, in the framework of a club, trade team, national federation or any other structure participating in races, in the preparation or support of *Riders* for sports competitions.

Major Event Organizations:

This term refers to the continental associations of *National Olympic Committees* and other international multi-sport organizations that function as the ruling body for any continental, regional or other international event.

Marker:

A compound, group of compounds or biological parameters that indicates the *Use* of a *Prohibited Substance* or *Prohibited Method*.

Medical Inspector:

Doping Control officer responsible for the Sample taking as described in these Anti-Doping Rules and in the *Procedural Guidelines*.

Metabolite:

Any substance produced by a biotransformation process.

Minor:

A natural Person who has not reached the age of majority as established by the applicable laws of his country of residence.

National Anti-Doping Organization:

The entity(ies) designated by each country as possessing the primary authority and responsibility to adopt and implement anti-doping rules, direct the collection of Samples, the management of test results, and the conduct of hearings, all at the national level. If this designation has not been made by the competent public authority(ies), the entity shall be the country's *National Olympic Committee* or its designee.

National Event / Competition / Race:

An *Event*, *Competition*, *Race* of the national calendar of each of the member federations of the UCI.

National Olympic Committee:

The organization recognized by the International Olympic Committee. The term *National Olympic Committee* shall also include the National Sport Confederation in those countries where the National Sport Confederation assumes typical *National Olympic Committee* responsibilities in the anti-doping area.

No Advance Notice:

A *Doping Control* which takes place with no advance warning to the *Rider* and where the *Rider* is continuously chaperoned from the moment of notification through *Sample* provision.

No Fault or Negligence:

The *Rider's* establishing that he did not know or suspect, and could not reasonably have known or suspected even with the exercise of utmost caution, that he had *Used* or been administered the *Prohibited Substance* or *Prohibited Method*.

No Significant Fault or Negligence:

The *Rider's* establishing that his fault or negligence, when viewed in the totality of the circumstances and taking into account the criteria for *No Fault or Negligence*, was not significant in relationship to the anti-doping rule violation.

Out-of-Competition:

Any *Doping Control* or fact which is not *In-Competition*.

Person:

A natural *Person* or an organization or other entity.

Possession:

The actual, physical possession, or the constructive possession (which shall be found only if the *Person* has exclusive control over the *Prohibited Substance/Method* or the premises in which a *Prohibited Substance/Method* exists); provided, however, that if the *Person* does not have exclusive control over the *Prohibited Substance/Method* or the premises in which a *Prohibited Substance/Method* exists, constructive possession shall only be found if the *Person* knew about the presence of the *Prohibited Substance/Method* and intended to exercise control over it. Provided, however, there shall be no anti-doping rule violation based solely on possession if, prior to receiving notification of any kind that the *Person* has committed an anti-doping rule violation, the *Person* has taken concrete action demonstrating that the *Person* no longer intends to have *Possession* and has renounced the *Person's* previous *Possession*.

Post-Competition Testing:

In-Competition Testing session that is organized following a *Race* or *Competition* for the purpose of testing *Riders* that participated in the *Race* or *Competition*.

Procedural Guidelines:

Documents established by the Anti-Doping Commission and regulating technical and operational parts of *Testing* pursuant to article 96; reference to these Anti-Doping Rules shall include reference to the *Procedural Guidelines* where applicable.

Prohibited List:

The List published by WADA and identifying the *Prohibited Substances* or *Prohibited Methods*.

UCI CYCLING REGULATIONS

Prohibited Method:

Any method so described on the *Prohibited List*.

Prohibited Substance:

Any substance so described on the *Prohibited List*.

Publicly Disclose or Publicly Report:

To disseminate or distribute information to the general public or persons beyond those persons entitled to earlier notification in accordance with these Anti-Doping Rules.

Race:

A cycling contest that produces a winner or a ranking according to the rules (for example: a one day road race; a stage or a half stage in a stage race, the 16th final of a track sprint race tournament, a cyclo-ball game).

Registered Testing Pool:

The pool of top level *Riders* established separately by the UCI and each National Anti-Doping Organization who are subject to both *In-Competition* and *Out-of-Competition Testing* as part of the UCI's or Organization's test distribution plan.

Rider:

A *Person* who participates as a cyclist in an *Event*, whether he is authorized to or not.

Rider's Support Personnel:

A *License-Holder* who is not a *Rider*.

Sample/Specimen:

Any biological material collected for the purposes of *Doping Control*.

Signatories:

Those entities signing the *Code* and agreeing to comply with the *Code*, including the International Olympic Committee, the UCI, International Paralympic Committee, *National Olympic Committees*, National Paralympic Committees, *Major Event Organizations*, *National Anti-Doping Organizations*, and WADA.

Specified Substance:

Prohibited Substance so identified on the *Prohibited List* pursuant to article 10.3 of the *Code*: "The *Prohibited List* may identify specified substances which are particularly susceptible to unintentional anti-doping rule violations because of their general availability in medicinal products or which are less likely to be successfully abused as doping agents".

Tampering:

Altering for an improper purpose or in an improper way; bringing improper influence to bear; interfering improperly to alter results or prevent normal procedures from occurring.

Target Testing:

Selection of *Riders* for *Testing* where specific *Riders* or groups of *Riders* are selected on a non-random basis for *Testing* at a specified time.

Testing:

The parts of the *Doping Control* process involving test distribution planning, *Sample* collection, *Sample* handling, and *Sample* transport to the laboratory.

Trafficking:

To sell, give, administer, transport, send, deliver or distribute a *Prohibited Substance* or *Prohibited Method* to any *Person* either directly or through one or more third parties, but excluding the sale or distribution (by medical personnel or by *Persons* other than a *Rider's Support Personnel*) of a *Prohibited Substance* for genuine and legal therapeutic purposes.

Use:

The application, ingestion, injection or consumption by any means whatsoever of any *Prohibited Substance* or *Prohibited Method*.

WADA:

The World Anti-Doping Agency.

(Appendix 2)

SELECTION OF RIDERS TO BE TESTED

(Article 121 of the Anti-Doping Rules)

(In the absence of specific instructions from the antidoping commission)

A. World Championships, Continental Championships, regional games

See appendix 3

B. Other events

I. ProTour (one day events)

• **General rule**

1. ProTour leader if he is present
2. The winner
3. Two riders selected at random by the inspector.

II. ProTour (stage races)

• **General rule**

1. ProTour leader after the first stage if he is present
2. ProTour leader after the last stage if he is present
3. The winner of the stage
4. The leader of the general classification after the stage
3. Two riders selected at random by the Inspector.

III. One day events (all disciplines)

• **General rule**

1. The winner
2. Two riders selected at random by the inspector.

• **World cup**

1. The winner of the race
2. The leader on the general classification of the world cup after the race
3. Two riders selected at random by the Inspector.

• **Half-stages**

1. The winner of the first half-stage
2. The winner of the second half-stage
3. One rider selected at random by the inspector for each half-stage.

• **Team events**

1. One rider selected at random by the inspector from the winning team
2. Two riders selected at random by the inspector from all other teams.

IV. Stage races (all disciplines, including prologues)

- **General rule**

1. The stage winner
2. The leader on general classification after the stage
3. Two riders selected at random by the inspector.

- **Team time trial stage**

1. One rider selected at random by the inspector from the winning team
2. The leader on general classification after the stage
3. Two riders selected at random by the inspector from all other teams.

- **Half-stages**

1. The winner of the first half-stage
2. The winner of the second half-stage
3. The leader on general classification after the second half-stage.

V. Specific time trial events

- **Individual**

1. The first three placed riders
2. Two riders selected at random by the inspector.

- **For teams**

1. One rider selected at random by the inspector from the winning team
2. One rider selected at random by the inspector from the second-placed team
3. One rider selected at random by the Inspector from each of four different randomly selected teams.

VI. Track events (all disciplines)

- **Individual**

1. The winner
2. One rider selected at random by the Inspector.

- **For teams**

1. One rider selected at random by the Inspector from the winning team
2. One rider selected at random by the Inspector from all other teams.

VII. Six-day races

1. One rider selected at random by the inspector from the winning team
2. Three riders selected at random by the inspector from three other different teams.

(text modified on 1.01.06).

**PLAN OF STANDARD TESTING STATION FOR
ANTIDOPING TESTS**

(Appendix 5)

EQUIPMENT OF THE DOPING CONTROL STATION

The doping control station must be equipped in such a way to facilitate the running of the tests. A suggested list non exhaustive of equipment is included in mentioned hereafter:

Equipment to be made available:

- Anti-doping kits*
- containers for the taking
- gloves
- provisional seal kits
- plastic bags in reserve
- packaging to send the kits
- adhesive tape
- envelopes
- string
- scissors
- drinks in large quantities (such as lemonade, mineral water, etc.)

* in sufficient number to allow the choice between two kits at least.

Furnishings

First room
(20-25 m²)

- 2 tables
- 8 chairs
- 1 refrigerator
- 1 waste bin
- 1 telephone connection (phone and fax).

Second room

- 2 tables
- 3 chairs
- toilet (WC)
- sink, shower
- 1 waste bin
- towels and soap
- ventilation or opening window.

(text modified on 1.01.06).

(Appendix 6)

On chemical self-copying paper in triplicate (1 original and 2 copies).
Original to UCI - Copy 1 (white) to the rider - Copy 2 (green) to the laboratory.

I. INTRODUCTION

1. This Award is the culmination of an exhaustive process of briefings and hearings, discussions amongst the parties, and numerous interventions by the Panel.

2. At issue is the charge by the United States Anti-Doping Agency ("USADA") that Tim Montgomery violated applicable IAAF anti-doping rules, notwithstanding that Mr. Montgomery never tested positive in any in-competition or out-of-competition drug test. As such, the issues raised in this so-called "non-analytical positive" case are, if not wholly novel, certainly not in the nature of issues arising in a typical "adverse analytical finding" (or "analytical positive") doping case. However, as explained more fully below, and to quote the Panel in the case of *USADA v. Michelle Collins* (another non-analytical positive case that arose in similar circumstances), "the straightforward application of legal principles to essentially undisputed facts leads to a clear resolution of this matter."

3. USADA seeks a four-year sanction of Tim Montgomery for participating in a wide-ranging doping conspiracy implemented by the Bay Area Laboratory Cooperative ("BALCO"). USADA charges that, for a period of several years, Mr. Montgomery used various performance-enhancing drugs provided by BALCO. As noted, Mr. Montgomery has never had a single drug test found to be a positive doping violation, but USADA's charges are based, in part, on all of the blood and urine tests at IOC-accredited and non-IOC-accredited laboratories that he has had in recent years. USADA also relies, among other things, on documents seized by the U.S. government from BALCO that have been provided to USADA; statements made by BALCO officials; and other documents.

4. According to USADA, BALCO was involved in a conspiracy the purpose of which was the distribution and use of doping substances and techniques that were either undetectable or difficult to detect in routine drug testing. BALCO is alleged to have distributed several types of banned doping agents to professional athletes in track and field, baseball and football. Among these were tetrahydrogestrinone ("THG"), otherwise known as "the Clear" by BALCO and its users. THG is a designer steroid that could not be identified by routine anti-doping testing until 2003, when a track and field coach provided a sample of it to USADA. It is undisputed that the Clear is a prohibited substance under the IAAF Rules.

5. On 3 September 2003, FBI agents searched BALCO's premises pursuant to search warrants. Approximately twenty-four agents searched BALCO's offices and seized hundreds of documents there and at other locations maintained by BALCO. The agents also seized samples of the Clear and other substances distributed by BALCO. During this raid, agents interviewed the company's President, Victor Conte, and other BALCO officials, who spoke about its activities and its customers. Mr. Conte named fifteen track and field athletes whom he alleged were clients of BALCO, including Mr. Montgomery, as well as other athletes from the NFL and Major League Baseball.

6. Following the BALCO raid, government agents obtained other documents, such as emails, through the use of subpoenas and other law enforcement mechanisms. Additional records were produced and created as part of the Grand Jury investigation, which resulted in the indictment of Mr. Conte, along with several alleged co-conspirators.¹ None of the evidence in this case derives from the Grand Jury proceedings. However, the BALCO documents were obtained by the U.S. Senate, which subsequently provided them to USADA.

7. As will be seen, the Panel's determination of the case against Mr. Montgomery turns on certain statements made by the Respondent himself which make it unnecessary for the Panel to determine whether the mass of other evidence adduced by USADA and derived in large measure from the BALCO documents, is also conclusive of the doping charges brought against him.

8. This Award is also the culmination of a process which saw two separate cases run essentially in parallel. Although the facts alleged in the present case and in the case of *USADA v. Chryste Gaines* differed in their detail, and separate submissions were filed by the parties in each case, both the nature of the charges brought against the Respondents and the substantive and procedural positions adopted by them throughout the period leading up to their respective hearings were so similar as to be virtually indistinguishable. Among other consequences, this meant that, but for the hearings on the merits, and with the consent of all parties, the two cases proceeded in lockstep. This is immediately apparent from a reading of the two Awards, which

¹ Mr. Conte pleaded guilty to several of the charges against him and, in October 2005, was sentenced to four months in prison plus four months of home confinement.

are being rendered simultaneously by the Panels (composed of the same arbitrators) in the two cases.

II. THE PARTIES

9. The Claimant, USADA, is the independent Anti-Doping Agency for Olympic sports in the United States and is responsible for managing the testing and adjudication process for doping control in that country. In that capacity, USADA conducts drug testing and results management for participants in the Olympic movement within the United States.²

10. The Respondent, Tim Montgomery ("**Mr. Montgomery**" or the "**Athlete**"), is an elite and highly successful American track and field athlete. As a sprinter, Mr. Montgomery has won numerous track and field titles, including World Championship and Olympic gold medals, as well as a world record.³

11. On 17 September 2004, The International Association of Athletics Federations (the "**IAAF**"), the international federation responsible for the sport of athletics worldwide, requested permission to appear in the arbitration as a party (i.e., as an intervener). In its request, the IAAF stated that, under IAAF Rules, should the Panel allow it to appear as a party, the Panel's award "... will be final and binding and no further reference may be made to the CAS" and, further, that "the IAAF is content for this to be the final decision on [the Athlete's] eligibility." The IAAF's request was granted by the Panel on 4 October 2004. On 22 October 2004, the IAAF specified that the sole issue in respect of which it might make submissions in the arbitration concerned "the position that may be adopted by the parties in relation to IAAF Rules and their proper construction." The Panel subsequently declared that "... the IAAF participating in [this case] as described above, the [award] rendered by the Panel shall be final and binding on the IAAF, without possibility of appeal."⁴ In the event, after

² See: United States Anti-Doping Agency Protocol for Olympic Movement Testing (effective 7 October 2002) (the "USADA Protocol"), Mission Statement and para. 1, Exhibit A to USADA's Request for Arbitration dated 5 July 2004.

³ The Panel notes that by letter dated 1 December 2005, counsel of record throughout the arbitration, Mr. Howard L. Jacobs and Ms. Jill A. Benjamin of the law firm *Forgey & Hurell, LLP*, and Ms. Cristina Arguedas and Ms. Julie Salomon of the law firm *Arguedas, Cassman & Headley*, notified the CAS that they were withdrawing as Mr. Montgomery's counsel in these proceedings.

⁴ All of this is described in detail in the Panel's 9 November 2004 correspondence to the parties, discussed further below.

considering the written submissions filed by Claimant and Respondent, the IAAF notified the CAS that it did not intend to make any independent submissions in the arbitration.

12. With the consent of Claimant and Respondent and of the Panel, several third parties were also granted permission by CAS to attend the hearings as "observers". These were: a representative of the World Anti-Doping Agency ("WADA"); John Ruger, the United States Olympic Committee ("USOC") Athlete Ombudsman; and a member of the staff of U.S. Congressman John Conyers, Jr. At the end of the day, Congressman Conyers chose not to send a representative to any of the hearings, WADA attended only the two preliminary hearings held on 15 December 2004 and 21 February 2005, and Mr. Ruger was the sole observer at the hearing on the merits.

III. PROCEDURAL BACKGROUND

A. USADA's "Charging Letter"

13. On 7 June 2004, USADA informed Respondent that it had received evidence which indicated that Mr. Montgomery was a participant in a doping conspiracy involving various elite athletes and coaches as well as BALCO. On the same date, USADA submitted the matter to its Anti-Doping Review Board (the "**Review Board**") pursuant to paragraph 9 (a) (i) of the USADA Protocol. In accordance with the provisions of that paragraph, the Athlete also submitted a lengthy and detailed submission on the matter to the Review Board.

14. By letter dated 22 June 2004 (the so-called "**Charging Letter**"), USADA informed Mr. Montgomery that, after consideration of the documents submitted to it by USADA and Mr. Montgomery, and in accordance with paragraph 9 (a) (i) (vi) of the USADA Protocol, the Review Board had determined that there existed "sufficient evidence against you to proceed with the adjudication process as set forth in [the USADA Protocol]."⁵ The charges against Respondent were set out in the Charging Letter, and reiterated in USADA's Statement of Claim, as follows:

⁵ Para 9 (a) (i) (vi) of the USADA Protocol reads as follows: "The Review Board shall consider the written information submitted to it and shall, by majority vote, make a recommendation to USADA with a copy to the Athlete whether or not there is sufficient evidence of doping to proceed with the adjudication process."

[A]t this time, and reserving all rights to amend the charge, USADA charges you with violations of the IAAF Anti-Doping Rules. (...) USADA charges that your participation in the Bay Area Laboratory Cooperative ("BALCO") conspiracy, the purpose of which was to trade in doping substances and techniques that were either undetectable or difficult to detect in routine testing, involved your violations of the following IAAF Rules that strictly forbid doping⁶:

- Rule 55.2

The offence of doping takes place when either:

- (i) a prohibited substance is present within an athlete's body tissues or fluids; or
- (ii) an athlete uses or takes advantage of a prohibited technique; or
- (iii) an athlete admits having used or taken advantage of a prohibited substance or a prohibited technique (See also Rule 56).

- Rule 56.3

Any person assisting or inciting others, or admitting having incited or assisted others, to use a prohibited substance, or prohibited techniques, shall have committed a doping offence and shall be subject to sanctions in accordance with Rule 60. If that person is not an athlete, then the Council may, at its discretion, impose an appropriate sanction.

- Rule 56.4

Any person trading, trafficking, distributing or selling any prohibited substance otherwise than in the normal course of a recognised profession or trade shall also have committed a doping offence under these Rules and shall be subject to sanctions in accordance with Rule 60.

- Rule 60.1

For the purpose of these Rules, the following shall be regarded as "doping offences" (see also Rule 55.2):

- (i) the presence in an athlete's body tissues or fluids of a prohibited substance;
- (ii) the use or taking advantage of forbidden techniques;

⁶ The text quoted is from the 2002 IAAF Rules. The version of the rules released in 2000 includes the following variations in language: Rule 60(1)(i) requires 'the finding in an athlete's body' [as opposed to 'the presence in an athlete's body tissues or fluids']; and Rule 60(1)(iii) excludes the phrase 'or having attempted to use.'

(iii) admitting having taken advantage of, or having used, or having attempted to use, a prohibited substance or a prohibited technique;

(...)

(vi) assisting or inciting others to use a prohibited substance or prohibited technique, or admitting having admitted or incited others;

(vii) trading, trafficking, distributing or selling any prohibited substance.

Specifically, the evidence confirms your involvement with the following prohibited substances and prohibited techniques: one or more substances belonging to the prohibited class of "Anabolic Steroids;" Testosterone/Epitestosterone Cream; EPO; Growth Hormone; and Insulin.

15. As regards the sanction for these alleged violations USADA stated as follows in its Charging Letter:

USADA applies the sanctions found in the rules of the relevant International Federations and the USOC Anti-Doping Policies. Therefore, at this time reserving all rights to amend the sanction at a later date, under the Rules of the IAAF, Division III, Rule 60, USADA is seeking the following sanction against you for your doping offense:

- A lifetime period of ineligibility beginning on the date you accept this sanction or the date of the hearing panel's decision;⁷
- The retroactive cancellation of all awards or additions to your trust fund to which you would have been entitled by virtue of your appearance and/or performance at any athletics meeting occurring between February 1, 2000 and the date your period of ineligibility begins, pursuant to Division III, Rule 60.5 of the IAAF Anti-Doping Rules; and,
- A lifetime period of ineligibility beginning on the date you accept this sanction or the date of a hearing panel's decision, from participating in a US Olympic, Pan American Games or Paralympic Games, trials or qualifying events, being a member of any US Olympic, Pan American Games or Paralympic Games team and having access to the training facilities of the United States Olympic Committee ("USOC") Training Centers or other programs and activities of the USOC including, but not limited to, grants, awards or employment pursuant to the USOC Anti-Doping Policies.

⁷ At the final hearing, by which time certain of the charges (in particular the charge of "trafficking") against the Respondent had been dropped, USADA requested that the Panel impose a *four-year* period of ineligibility on Mr. Montgomery.

B. The Decision to Proceed Directly to CAS

16. In response to the Charging Letter, Mr. Montgomery notified USADA on 28 June 2004 that, in conformity with paragraph 9 (b) (iv) of the USADA Protocol, he elected to "bypass the domestic hearing process" described in paragraph 9 (b) (ii) of the USADA Protocol and "proceed directly to a single final hearing before the Court of Arbitration for Sport."⁸

17. The Respondent did not state in his letter, though the Panel considers it significant to note, that paragraph 9 (b) (iv) of the USADA Protocol provides that upon an athlete making such an election, "[t]he CAS decision shall be final and binding on all parties and shall not be subject to further review or appeal."

C. Commencement of the Arbitration and Constitution of the Panel

18. On 5 July 2004, Claimant submitted its Request for Arbitration to the CAS. The Request for Arbitration substantially reprised the allegations set out in USADA's 22 July 2004 Charging Letter, and identified Peter Leaver, QC, barrister, of London, England, as USADA's party-appointed arbitrator.

19. The Request for Arbitration also noted the parties' agreement that, in the event that Mr. Montgomery were to qualify for the US Olympic team for the 2004 Summer Games in Athens the following month, the arbitration proceedings would be expedited.⁹

20. Mr. Montgomery submitted his Answer to USADA's Request for Arbitration on 6 July 2004. In his Answer, the Athlete provided a brief statement of his defence and named Christopher L. Campbell, Esq., attorney-at-law, of San Francisco, U.S.A, as his party-appointed arbitrator.

21. The two party-appointed arbitrators subsequently selected L. Yves Fortier, CC, QC, barrister and solicitor, of Montréal, Canada, to serve as President of the Panel.¹⁰

⁸ Mr. Montgomery's letter of 28 June 2004 is filed as Exhibit B to USADA's Request for Arbitration.

⁹ In the event, Mr. Montgomery did not qualify for the US Olympic team.

¹⁰ The constitution of the Panel was formally notified to the parties by means of an "Order of Procedure" issued by the CAS on 8 September 2004. See below.

22. In due course, the CAS appointed Stephen L. Drymer, barrister and solicitor, of Montréal, Canada, to assist the Panel in the capacity of *ad hoc* clerk.

D. Initial Stage of the Proceedings and the CAS Order of Procedure (August - October 2004)

23. Far from "expediting" matters, as might originally have been their intention, the parties instead proved unable, during the initial stage of the arbitration, to collaborate with each other and the Panel as required to speed matters along. Having observed as much, the Panel acknowledges the unique and complex nature of the issues raised in this case, which no doubt meant that additional time was required for the parties to elucidate (let alone for the Tribunal to determine) the numerous substantive and procedural issues which arose in the course of the proceedings.

24. On 8 September 2004, the CAS issued its standard "Order of Procedure" addressing such matters as the jurisdiction of the CAS, the composition of the Panel, provisions regarding the costs of the arbitration and a statement concerning the confidentiality of the proceedings. The Order of Procedure also established a timetable for the filing of written submissions by the parties in accordance with article R44.1 of the CAS Code of Sports-related Arbitration (the "CAS Code"), leading to a hearing on the merits in San Francisco during the week of 1-5 November 2004. (As discussed below, that timetable quickly proved to be unfeasible and was in due course modified.)

25. The 8 September 2004 Order of Procedure further confirmed that the conduct of the arbitration was governed by articles R38 and following of the CAS Code, that is, by the CAS rules applicable to "Ordinary" (first instance) arbitrations as opposed to "Appeal" arbitrations.

26. The parties subsequently filed their respective written submissions – a Statement of Claim and a Response, together with supporting evidence – as required by the Order of Procedure.

27. As indicated above, the period leading to the planned 1 November 2004 hearing was characterized by an acrimonious flurry of correspondence, requests, objections, accusations and counter-accusations, motions and applications, the overall effect of which ultimately led both parties to request that the November 2004 hearing dates be vacated.

28. Among the procedural decisions and orders that the Panel was called upon to render during this period, several deserve mention.

- On 20 September 2004, the Panel denied two motions brought by USADA, one to compel the giving of consent by Mr. Montgomery for USADA to access certain medical records, and the second to compel Mr. Montgomery to answer certain "requests for admissions". The Panel also addressed a motion by USADA to issue subpoenas to various individuals. In this latter regard, the Panel agreed with USADA's submission that it has the power to issue subpoenas enforceable by United States courts; however, it requested the parties to provide additional briefing concerning the form of such subpoenas taking into account the provisions of article R44.3 of the CAS Code as well as Article 7 of the U.S. *Federal Arbitration Act* and Rule 45 of the U.S. *Federal Rules of Civil Procedure*.
- On 26 September 2004, the Panel signed and issued a "Stipulated Protective Order" negotiated by the parties governing the disclosure of confidential information by USADA to Respondent.
- On 7 October 2004, having considered the parties' submissions on the matter of the subpoenas requested by USADA, the Panel issued subpoenas to five individuals compelling their attendance (and in certain cases requiring the production of specified documents by them) at the 1 November hearing.¹¹
- On 19 October 2004, the Panel denied the parties' request (originally formulated by Respondent and consented to by Claimant), that the hearing on the merits be postponed from 1 November to a date "to be determined." The Panel instead reconfirmed that the hearing would commence on 1 November 2004. The Panel informed the parties that the first issue to be addressed at that hearing would be the determination of an appropriate and detailed schedule for the presentation of the parties' evidence; subsequently, the Panel would receive documents from those witnesses to whom subpoenas will have been issued and thereafter, and subject to any

¹¹ The Panel denied USADA's requests for subpoenas to be issued to various reporters as well as to the Respondent himself.

determinations made with respect to a detailed hearing schedule, the evidentiary phase of the hearing would commence, it is being understood that additional hearing days would also be scheduled.

- On 20 October 2004, the Panel responded to Mr. Montgomery's motion for issuance of subpoenas dated 15 September 2004. As in the case of the subpoenas previously requested by USADA, the Panel granted the Athlete's request by issuing subpoenas to several individuals compelling their attendance and requiring the production of documents by them at the hearing set to commence on 1 November 2004.

29. One further occurrence during this period deserves mention. On 26 October 2004, the parties entered into a "joint stipulation" in which they noted the existence of numerous disagreements regarding "threshold procedural and evidentiary issues, the resolution of which are fundamental to determining the most efficient presentation of [this case]" and acknowledged their inability "to reach any agreement on these procedural and evidentiary issues that would facilitate the orderly and efficient presentation of [this case]." The stipulation further recorded the parties' agreement to vacate the hearing dates during the week of 1 November as well as their agreement regarding a (partial) procedural timetable leading to a hearing to be scheduled at an undetermined date in 2005. The Panel responded to this development by a letter dated 28 October 2004. The Panel expressed its "surprise at this last minute development." It informed the parties that, in the circumstances, the hearing on the merits clearly could not commence on 1 November, yet it nonetheless ordered the parties' legal representatives to meet with the Panel in San Francisco on 1 November "in order to discuss fully all outstanding procedural and evidentiary issues and seek to determine a reasonable calendar for the future conduct of [this arbitration]."

E. First Preliminary Hearing: Procedural Timetable and Related Issues (1 November 2004)

30. A preliminary hearing was accordingly held in San Francisco on 1 November 2004. The outcome of that hearing is described in detail in a letter to the parties dated 9 November

2004, in which the Panel confirmed a series of procedural orders issued orally during the hearing itself.¹²

31. As noted in the Panel's 9 November letter, the hearing "was considered necessary by the Panel in view of what it believed to be insufficient progress made by the parties themselves – as illustrated, for example, in their Joint Stipulation of 26 October 2004 – in establishing a clear timetable for the fair and efficient determination of [this case]." The procedural orders issued on 1 November, and confirmed in writing on 9 November, addressed a series of issues ranging from the re-issuance of subpoenas previously issued at the request of the parties,¹³ the identity of the individuals authorized to participate in the arbitration as observers or interveners, as well as, most importantly, a list of outstanding procedural and evidentiary issues raised by the parties and a detailed timetable for the briefing and hearing of those issues.

F. Second Preliminary Hearing: Jurisdiction of the Panel (15 December 2004)

32. In accordance with the timetable established on 1 November 2004 and confirmed in writing on 9 November, a preliminary hearing was held, in Montreal, on 15 December 2004 on the matter of a Motion brought by the Athlete to dismiss the case on the ground that the CAS lacked jurisdiction.

33. The nature of the parties' submissions and the positions taken by them both in writing and at the hearing are described in the Panel's Award on Jurisdiction dated 9 February 2005. For present purposes it suffices to note that, for the reasons set out in that Award, the Panel dismissed Respondent's Motion and affirmed its jurisdiction in this matter.

G. Third Preliminary Hearing: Evidentiary Issues and Objections (21 February 2005).

34. A further, and final, preliminary hearing was held, in Montreal, on 21 February 2005 for the purpose of hearing the parties' submissions on a variety of evidentiary issues and objections raised by Respondent. Once again, reference is made to the detailed Decision on

¹² It is noted that a court reporter was engaged to record the proceedings of the 1 November 2004 hearing, and that a transcript of those proceedings was provided to the parties and to the CAS.

¹³ None of the individuals to whom subpoenas had been issued in fact appeared at the 1 November hearing and neither party produced any of the documents requested of these individuals.

Evidentiary and Procedural Issues rendered by the Panel on 4 March 2005 in respect of the matters addressed at that hearing.

35. With the Panel's 4 March 2005 Decision, the nature of the allegations against the Respondent was clarified, certain additional submissions were requested of the parties and, in short, the path toward the hearing on the merits was cleared.

36. The Panel's Decision on Evidentiary and Procedural Issues also addressed the question of the standard of proof applicable in the present case, which had been in dispute as between the parties. In view of the importance of the issue the Panel considers it apposite to reproduce the relevant passages of its 4 March 2005 Decision, which are as follows:

Standard of Proof

There is no dispute as to which of the parties, whether Claimant or Respondents, bears the onus of establishing the charges that have been levelled against Mr. Montgomery and Ms. Gaines in these cases. All parties accept that USADA bears the burden of proof in respect of its claims.

There is no such common understanding, however, in respect of the standard of the proof to be made by USADA in order for it to succeed – that is, whether USADA must prove its claims beyond reasonable doubt, as advocated by Respondents, or whether it need only make proof on the balance of probability.

The athletes' submissions are based on the argument (to quote from Mr. Montgomery's Motion on Burden of Proof, at p. 2) that "the U.S. Supreme Court has held that the burden of proof is a substantive rule [that cannot be applied retroactively]," and on the fact that "[p]rior to March 2004, IAAF Rule 59.6 provided that in all doping hearings, 'the Member shall have the burden of proving, beyond reasonable doubt, that a doping offense has been committed'." As further summarised by the athletes' counsel during the 21-22 February 2005 hearing, given that "that is what the new Rules say, you don't even have to consider the substantive/procedural issue."

As set out in its Statements of Claim, USADA's claims against the athletes for violations of IAAF Rules concern allegations that Respondents engaged in systematic doping "commencing in February 2000" (in Mr. Montgomery's case) and "commencing in September 2000" (as regards Ms. Gaines); and, as noted above, USADA refers specifically to alleged violations of the 2002 IAAF Rules. As of 1 March 2004, the IAAF implemented the provisions of the World Anti-Doping Code in new IAAF Anti-Doping Rules, including the provision (Article 3.1 of the World Anti-Doping Code: "Burdens and Standards of Proof") that "[t]he standard of proof shall be whether the Anti-Doping Organization has established an anti-doping rule violation *to the comfortable satisfaction of the hearing body, bearing mind the seriousness of the allegation which is made.*" (Emphasis added)

USADA, not surprisingly, sees things differently than the Respondents. It acknowledges (at p. 42 of its 9 February 2005 Response Brief) that what it calls “[t]he old ‘beyond reasonable doubt’ standard” was replaced by the IAAF as of 1 March 2004. The crux of USADA’s argument is that “[t]he introduction to the new IAAF Rules state that the new rules ‘shall not be applied retrospectively to doping matters pending at 1 March 2004’; *by negative implication, this introductory statement suggests that the new rules may be applied to doping charges initiated after March 1, 2004.*” (Emphasis added) USADA goes on to challenge the Respondents’ view that the standard of proof is a substantive, as opposed to a procedural, rule; and it refers to U.S. case law as well as CAS precedent in support of the principle that the criminal law standard of proof is inapplicable to these proceedings.

As often becomes evident when the question of standard of proof is debated, the debate looms larger in theory than practice. Counsel for all parties concurred with the views expressed by the members of the Panel during the 21-22 February 2005 hearing to the effect that even if the so-called “lesser”, “civil” standard were to apply – namely, proof on the balance of probability, or, in the specific context in which these cases arise, proof to the *comfortable satisfaction* of the Panel *bearing mind the seriousness of the allegation which is made* (what might be called the “comfortable satisfaction” standard) – an extremely high level of proof would be required to “comfortably satisfy” the Panel that Respondents were guilty of the serious conduct of which they stand accused.

Even under the traditional civil model, there is no absolute standard of proof. Built into the balance of probability standard is a generous degree of flexibility that relates to the seriousness of the allegations to be determined. In all cases the degree of probability must be commensurate with and proportionate to those allegations; the more serious the allegation the higher the degree of probability, or “comfort”, required. That is because, in general, the more serious the allegation the less likely it is that the alleged event occurred and, hence, the stronger the evidence required before the occurrence of the event is demonstrated to be more probable than not. Nor is there necessarily a great gulf between proof in civil and criminal matters. In matters of proof the law looks for probability, not certainty. In some criminal cases, liberty may be involved; in some it may not. In some civil cases – as here – the issues may involve questions of character and reputation and the ability to pursue one’s chosen career that can approach, if not transcend in importance even questions of personal liberty. The gravity of the allegations and the related probability or improbability of their occurrence become in effect part and parcel of the circumstances which must be weighed in deciding whether, on balance, they are true.

Without deciding the matter, the Panel notes that it appears that this is the very sort of approach contemplated by Article 3.1 of the World Anti-Doping Code, which refers to a standard of proof “bearing in mind the seriousness of the allegation which is made” and which further states that “[t]his standard of proof in all cases is greater than a *mere* balance of probability ...” (Emphasis added)

From this perspective, and in view of the nature and gravity of the allegations at issue in these proceedings, there is no practical distinction between the standards of proof advocated by USADA and the Respondents. It makes little, if indeed any, difference whether a “beyond reasonable doubt” or “comfortable satisfaction” standard is applied to determine the claims against the Respondents. This will

become all the more manifest in due course, when the Panel renders its awards on the merits of USADA's claims. Either way, USADA bears the burden of proving, by strong evidence commensurate with the serious claims it makes, that the Respondents committed the doping offences in question.

H. The Hearing on the Merits (6 - 10 June 2005)

37. On 28 April 2005, Claimant filed a motion to postpone the hearing that was scheduled on 6 June 2005. USADA requested that the hearing be postponed until after the conclusion of the BALCO criminal trial so as to ensure, to the extent possible, that Victor Conte (who refused to testify in these proceedings prior to the completion of the BALCO trial) and IRS Agent Jeff Novitzky (whose testimony in these proceedings prior to the BALCO trial was "uncertain") would be available to testify before the Panel. Claimant's Motion was denied, as much for the fact that USADA had long been aware of the possibility that Messrs. Conte and Novitzky might not be available to testify in the arbitration as for the patent unfairness to Respondent that would be caused by any additional delay in the resolution of the charges brought against him.

38. As previously agreed and set out in the Panel's Orders of 1 and 9 November 2004, the hearing on the merits in this case took place in San Francisco during the 5-day period from 6-10 June 2005.

39. At the hearing, the Panel heard oral argument from both parties. It also heard the evidence of the following witnesses:

For USADA

- Dr Larry Bowers, USADA's Senior Manager Director, who testified regarding the evidence discovered during the BALCO investigation as well as regarding Mr. Montgomery's blood and urine testing;
- IRS Agent Jeff Novitzky, who gave evidence regarding the BALCO investigation and the documents discovered in the course of that investigation;

- Ms. Kelli White, a former elite American athlete who has admitted to doping with the assistance of BALCO, who testified regarding an alleged admission made to her by Mr. Montgomery;
- Dr Hans Geyer, an expert who testified with respect to Respondent's urine test results;
- Dr Richard Clark, an expert called to analyze Mr. Montgomery's urine test results submitted by USADA; and
- Dr Michael Sawka, an expert called by USADA to give evidence regarding Mr. Montgomery's blood test results.

For Respondent

- Dr. David Black, President and Laboratory Director of Aegis Sciences Corp. and Aegis Analytical Laboratories, who provided expert evidence regarding the analytical laboratory data (blood and urine tests) produced by USADA; and
- Dr. James Stray-Gundersen, an expert who testified regarding the blood testing results for Mr. Montgomery produced by USADA.

40. Although Mr. Montgomery's counsel cross-examined each of the witnesses produced by USADA, the Athlete called no fact witnesses of his own nor did he himself give evidence.

IV. THE CASE AGAINST MR. MONTGOMERY

I. Applicable IAAF Rules

41. As set out in USADA's Charging Letter and Statement of Claim, the charges brought against the Respondent concern alleged offences under IAAF Rules 55.2, 56.3, 56.4, and 60.1 (reproduced in full in paragraph 14 above). As noted, these charges are brought under the 2002 edition of the IAAF Rules (IAAF Official Handbook 2002-2003), which are applicable.

42. Notwithstanding the breadth of the charges brought against Mr. Montgomery – comprising the *presence, use* and *admission* of use of prohibited substances or techniques (Rules 55.2 and 60.1), *assisting* and *inciting* others to do so (Rules 56.3 and 60.1), and *trafficking* in prohibited substances (Rules 56.4 and 60.1) – it became increasingly apparent in the course of the proceedings, that the thrust of USADA's case concerns allegations of the use of prohibited substances and techniques (including alleged admissions of use and evidence of the presence of prohibited substances in the Athlete's body) as opposed to the "assisting or inciting" and "trafficking" charges. Ultimately, these charges were dropped by USADA.

J. USADA's 7 Types of Evidence

43. As presented by USADA at the hearing, the evidence of doping by Mr. Montgomery consisted of what Claimant referred to as 7 types of evidence:

- (1) Blood test results from a Mexican laboratory in February 2000 which allegedly show Mr. Montgomery's testosterone level doubling in the course of one day;
- (2) Documents extracted from the files seized from BALCO which, according to USADA, "individually or when linked together established Montgomery's doping";
- (3) Evidence of the suppression and rebound of endogenous steroids in Respondent's urine, as shown in a table depicting test results reported by IOC-accredited and BALCO Laboratories on 56 occasions between March 1999 and September 2004;
- (4) Alleged abnormal blood test results on 5 occasions between November 2000 and July 2001;
- (5) Respondent's alleged admission to Kelli White that he had used a prohibited substance known colloquially as the "Clear";
- (6) So-called admissions against interest, which implicated Mr. Montgomery, made by the President of BALCO, Victor Conte, in interviews with investigative authorities as well as the media; and

- (7) Reports in the San Francisco Chronicle supposedly based on secret grand jury testimony by Mr. Montgomery in which he admits to using various prohibited substances.

44. All of the foregoing evidence was challenged by the Respondent. This includes the reliability and veracity of statements regarding Mr. Montgomery contained both in statements that may have been made by Victor Conte and in documents found in his files, the propriety of the Panel considering newspaper reports allegedly derived from secret Grand Jury testimony, the credibility of Ms. White's testimony before the Panel in this arbitration and, significantly, the authenticity, reliability, interpretation and weight of test results conducted by non-IOC-accredited labs as well as the overall interpretation of the numerous blood and urine test results for Mr. Montgomery.

45. The Panel has wrestled with the question whether, in the circumstances, it should address in this Award each element of USADA's case against Mr. Montgomery, including each of what USADA calls its "7 types of evidence" of doping by the Athlete. On balance, the Panel has determined not to do so for the simple reason that it is unnecessary. This is because the Panel is unanimously of the view that Mr. Montgomery in fact admitted his use of prohibited substances to Ms. White, as discussed in more detail below, on which basis alone the Panel can and does find him guilty of a doping offence. The fact that the Panel does not consider it necessary in the circumstances to analyse and comment on the mass of other evidence against the Athlete, however, is not to be taken as an indication that it considers that such other evidence could not demonstrate that the Respondent is guilty of doping. Doping offences can be proved by a variety of means; and this is nowhere more true than in "non-analytical positive" cases such as the present.

K. Kelli White's Testimony

46. As mentioned, Ms. White has admitted to doping and has accepted a two-year sanction as a result. Having seen Ms. White and heard her testimony, including in response to questions put to her by counsel and the Panel, the members of the Panel do not doubt the veracity of her evidence. She answered all questions, including in relation to her own record of doping, in a forthright, honest and reasonable manner. She neither exaggerated nor sought to play down any aspect of her evidence. Clearly an intelligent woman, she impressed the

Panel with her candour as well as her dispassionate approach to the issues raised in her testimony and regarding which she was questioned by counsel and members of the Panel. In sum, the Panel finds Ms. White's testimony to be wholly credible.

47. According Ms. White's evidence, in March 2001, while at an international meet in Portugal (no exact date was provided by the witness) she and Mr. Montgomery had "a small discussion about whether or not the Clear made our calves tight." Mr. Montgomery asked Ms. White, "Does it make your calves tight?" Ms. White responded in the affirmative. Mr. Montgomery, still in her presence, then placed a telephone call to someone who may or may not have been Mr. Conte (Ms. White believes that it was Mr. Conte) to whom he relayed the information that "she said that it makes her calves tight too". According to Ms. White, there was not the slightest doubt as to the substance about which she and Mr. Montgomery were speaking and which they both acknowledged had the effect of making their calves tight: they were talking about the Clear.

48. It is essential to note that this evidence of what USADA claims constitutes a direct admission of Mr. Montgomery's guilt, is uncontroverted.

49. Counsel for Respondent may have questioned Ms. White's motives in offering her testimony concerning Mr. Montgomery's use of the Clear and, more generally, his relationship with BALCO. They may have sought (without success) to impugn her honesty and to draw attention to the witness' own history of involvement with BALCO and her efforts to conceal that involvement. However, the Panel has already declared its finding with respect to Ms. White's credibility as a witness in these proceedings and its view that she is telling the truth.

50. What counsel for Mr. Montgomery did not do was in any way undermine Ms. White's evidence regarding her conversation with Mr. Montgomery in March 2001. The evidence of that conversation, which the Panel considers to be clear and compelling, thus stands uncontroverted. It is also, as indicated above, sufficient in and of itself to find Respondent guilty of doping.

L. Mr. Montgomery's Decision Not to Testify

51. Of course, as noted by USADA's counsel during closing argument: "It would be a real different issue if Tim Montgomery took the stand and said '*no, no, when I said "it" I meant*

something else'." It might indeed have affected the Panel's appreciation of Ms. White's evidence had Respondent chosen to provide the Panel with a different explanation of their March 2001 conversation or had he denied that the conversation took place as described by the witness. The fact remains that he did not.

52. The Respondent's decision not to testify at his hearing did not come as a surprise. Indeed, the decision had been communicated to USADA and the Panel by Mr. Montgomery's counsel early in the proceedings. Nor is there any dispute as to Respondent's right to decide not to testify. It is common ground that Mr. Montgomery was fully within his rights to testify in his own defence, or not, as he saw fit. Where the parties differ, however, is with respect to the question (on which extensive pre-hearing submissions and authorities were filed and arguments were made during the hearing) whether the Panel has the authority to draw an adverse inference from Mr. Montgomery's decision not to testify in the arbitration; and, if it does have the power to do so, whether such an inference should be drawn in this case.

53. On 17 September 2005, the Panel advised the parties that, having considered their written and oral arguments and the legal authorities filed by them for and against the drawing of an adverse inference, and after deliberation, it found that "it does have the right and power to draw an adverse inference from Mr. Montgomery's refusal to testify. More particularly, it may draw adverse inferences in respect of allegations regarding which USADA has presented evidence that would normally call for a Response from the Respondent himself, and not merely from his experts or counsel." The Panel further informed the parties that it had not yet determined whether it would draw any such inferences and that its deliberations had been suspended so as to allow Respondent the opportunity to reconsider, in the circumstances, his decision not to testify.¹⁴

¹⁴ As explained in the Panel's 17 September letter, this somewhat unusual procedure was considered necessary and appropriate in the circumstances, so as to preserve the procedural harmony as between Mr. Montgomery's and Ms. Gaines' cases. As the Panel explained to the parties (and as USADA was well aware, in its capacity as the Claimant in the Gaines arbitration), because of the different manner in which events at her hearing unfolded, Ms. Gaines had had the opportunity to address the question whether, in the event that the Panel were to find that it may draw adverse inferences from her refusal to testify, she would wish to be so informed in order to be able to reconsider her decision. Ms. Gaines' answer was "No". The same opportunity for Mr. Montgomery to address this question had not arisen during his hearing the month before.

54. It is noted that in the case of *USADA v. Michelle Collins* the Arbitral Tribunal found that it "may draw certain adverse inferences" from the Respondent's refusal to testify, though "there is no rule obligating a Tribunal to draw an adverse inference." Indeed, the Tribunal went on to hold that "no adverse inference is necessary" given that the weight of the evidence "is already adverse to Collins so no further adverse inference need be drawn".

55. The situation is similar in the present case. Mr. Montgomery has been provided every conceivable opportunity to provide an exculpatory explanation of his own statements evidencing his guilt. He has had ample opportunity to deny ever making such statements. But because he has not offered any evidence of his own concerning his admission to Ms. White of his use of the Clear, the Panel can only rely on the testimony of Ms. White. That testimony is more than merely adverse to Mr. Montgomery; it is fatal to his case. In the circumstances, faced with uncontroverted evidence of such a direct and compelling nature, there is simply no need for any additional inference to be drawn from the Respondent's refusal to testify. The evidence alone is sufficient to convict.

V. DECISION

M. The Doping Offence

56. In its 4 March 2005 Decision on Evidentiary and Procedural Issues, the Panel observed that "it makes little, if indeed any difference, whether a 'beyond reasonable doubt' or 'comfortable satisfaction' standard is applied to determine the claims against the [Respondent] ... Either way, USADA bears the burden of proving, by strong evidence commensurate with the serious claims it makes that the [Respondent] committed the doping offences in question."

57. USADA has met this standard. The Panel has no doubt in this case, and is more than comfortably satisfied, that Mr. Montgomery committed the doping offence in question. It has been presented with strong, indeed uncontroverted, evidence of doping by Mr. Montgomery, in the form of an admission contained in his statements made to Ms. White and to others while in her presence. On this basis, the Tribunal finds Respondent guilty of a doping offence. In particular, the Panel finds Mr. Montgomery guilty of the offence of admitting having used a prohibited substance under IAAF Rules 55.2(iii) and 60.1(iii).

N. The Sanction

58. By way of sanction, USADA commenced this case by informing Mr. Montgomery that it intended to request, and indeed it requested from the Panel, "a lifetime period of ineligibility beginning on the date you accept this sanction or the date of the hearing panel's decision."¹⁵ It subsequently amended this request (including as a consequence of its withdrawal of the "trafficking" allegations against Respondent) and, at the close of the hearing, requested a four-year period of ineligibility.

59. USADA request is based on IAAF Rule 60.2 (a) (i), which provides that for a first offence under Rule 60.1(iii) (which includes the offence of admitting having used a prohibited substance) an athlete shall be ineligible "for a minimum of two years from the date of the hearing at which it is decided that a Doping Offence has taken place."

60. In the circumstances, the Panel finds that Mr. Montgomery's admission of his use of prohibited substances merits a period of ineligibility under IAAF Rules of two years.

61. This period of ineligibility shall commence to run as of 6 June 2005, being the first day of Mr. Montgomery's hearing. The Panel is of the view that this date of commencement of the sanction is fair and appropriate in the particular circumstances of this case in view of the numerous delays in the hearing process unattributable to the Athlete, including as a result of the agreement of all parties that Mr. Montgomery's and Ms. Gaines' cases should be run in tandem. Although this agreement entailed significant efficiencies overall, and doubtless permitted the two cases to be heard and decided (by the same Panel) more quickly than if they had been conducted sequentially, it inevitably meant that there would be some additional delay before either case could be heard.¹⁶

62. In addition to the two-year sanction already discussed, the Panel orders the retroactive cancellation of all of Mr. Montgomery's results, rankings, awards and winnings as of 31 March 2001 (as noted above, Ms. White did testify as to the exact date during the month of March, 2001 on which Mr. Montgomery admitted his use of the Clear, and the Panel thus

¹⁵ Quoted from USADA's Charging Letter : see above.

¹⁶ The agreement to maintain what the Panel has had occasion to refer to as the "procedural harmony" between the two cases also meant that the decision in the first of the two cases to be heard – which, as agreed between the parties would be Mr. Montgomery's case – would be issued by the Panel at the same time as its decision in the second case.

considers it reasonable that the last day of the month in question be selected for this purpose). In this regard, IAAF Rule 60.5 provides: "Where an athlete has been declared ineligible he shall not be entitled to any award or addition to his trust fund to which he would have been entitled by virtue of his appearance and/or performance at the athletics meeting at which the doping offence took place, or at any subsequent meetings."

VI. CONCLUSION

63. In its introduction to the present Award, the Panel described the relative novelty of this case, in which USADA sought to prove a doping offence in the absence of any "adverse analytical finding". It must also be noted that this case can be distinguished from those of other elite track athletes involved with BALCO, such as Ms. White, Alvin Harrison and Regina Jacobs, who admitted their guilt to USADA in the context of anti-doping proceedings.

64. The Panel would add, in conclusion, that there is no reason to believe that the world of sport has seen the last of this sort of "no adverse analytical finding" case. It must constantly be borne in mind, as noted above, that doping offences can be proved by a variety of means. In this regard, the Panel concurs with the observation expressed in the Comitato Olimpico Nazionale Italiano ("CONI") matter, that "in anti-doping proceedings other than those deriving from positive testing, sports authorities do not have an easy task in discharging the burden of proving that an anti-doping rule violation has occurred, as no presumption applies." However, the Panel also concurs wholeheartedly with the exhortation of the CONI Panel, which wrote as follows in the concluding passage of its Award, a declaration that this Panel adopts as its own:

In any event, the undeniable circumstance that the conviction for doping offences is more difficult when the evidence is other than positive testing must not prevent the sports authorities from prosecuting such offences, as already remarked, with the outmost earnestness and eagerness, using any available method of investigation. In the end, it will be up to the adjudicating body having jurisdiction over the matter – which, according to Article 8 of the WADC, must always be a "fair and impartial hearing body" – to determine case by case whether the standard of proof of Article 3.1 of the WADC has been met and the burden of proof has been discharged, or not, by the prosecuting sports authority.

VII. COSTS

65. The issue of costs is dealt with in paragraph 12 of the 8 September 2004 CAS Order of Procedure as follows, in terms that neither party has asked the Panel to disturb:

12.1 In accordance with art. 64 of the Code and with art. 9 b (iv) of the USADA Protocol, the costs of this arbitration will be borne by USADA.

12.2 Each party is responsible for the fees and costs of its lawyer and such costs as arise from the appearance of witnesses whose hearing has been requested.

VIII. PUBLICATION OF THE AWARD

66. In accordance with clause 13 of the Order of Procedure dated 8 September 2004, the award and a press release setting forth the outcome of the proceedings shall be made public by the CAS.

ON THESE GROUNDS

The Panel unanimously finds and orders as follows:

1. Respondent is guilty of the offence of admitting having used a prohibited substance under IAAF Rules 55.2(iii) and 60.1(iii);
2. The following sanctions shall be imposed on Respondent:
 - a. A period of ineligibility under IAAF Rules for two years commencing as of 6 June 2005, including his ineligibility from participating in U.S. Olympic, Pan American or Paralympic Games, trials or qualifying events, being a member of any U.S. Olympic, Pan American or Paralympic Games team and having access to the training facilities of the United States Olympic Committee ("USOC") Training Centers or other programs and activities of the USOC including, but not limited to, grants, awards, or employment pursuant to the USOC Anti-Doping Policies;
 - b. The retroactive cancellation of all awards or additions to Respondent's trust fund to which he would have been entitled by virtue of his appearance and/or performance at any athletics meeting occurring between 31 March 2001 and the date of this Award;
3. The costs of the arbitration, to be determined and notified to the parties by the Secretary General of the CAS in accordance with article R 64.4 of the CAS Code, shall be borne by USADA;
4. Each party shall bear all of its own costs, including the fees and expenses of its lawyers and witnesses;
5. This Award deals definitively with all charges brought against Respondent by Claimant in this arbitration. All charges not expressly dealt with herein are dismissed.

Lausanne, 13 December 2005

THE COURT OF ARBITRATION FOR SPORT

SENTENCE ARBITRALE

rendue par le

TRIBUNAL ARBITRAL DU SPORT

siégeant dans la composition suivante :

Président : Maître Jan **Paulsson**, avocat à Paris, France
Arbitres : Maître Olivier **Carrard**, avocat à Genève, Suisse
Maître José Juan **Pintó**, avocat à Barcelone, Espagne
Greffier ad hoc : Maître Shaparak Saleh, avocat à Paris, France

dans l'arbitrage entre

L'Union Cycliste Internationale (UCI), Aigle, Suisse
représentée par Maître Philippe Verbiest, avocat à Leuven, Belgique

contre

Monsieur Iñigo Landa Intxaurreaga, Espagne
représenté par Maître Carmen Coello de Portugal Silva et Maître Immaculada Herranz
Perlado, avocats à Madrid, Espagne

et

Real Federación Española de Ciclismo (RFEC), Madrid, Espagne
représentée par Maître José Antonio del Valle Herán, avocat à Madrid, Espagne

* * * * *

I. LES FAITS

1. L'Union Cycliste Internationale (l'**UCI**) est l'association des fédérations nationales du cyclisme. Elle a pour but la direction, le développement, la réglementation, le contrôle et la discipline du cyclisme. Le système de contrôle antidopage mis en place par l'UCI comprend notamment le Règlement du Contrôle Antidopage (le **RCAD**), la liste des classes de substances dopantes et des méthodes de dopage, la liste des épreuves internationales à contrôler ainsi que la liste des laboratoires accrédités.
2. La Real Federación Española de Ciclismo (la **RFEC**), fédération nationale espagnole chargée du cyclisme et dotée d'un règlement disciplinaire au niveau national, est membre de l'UCI.
3. Monsieur Iñigo Landaluce Intxaurreaga (**Monsieur Landaluce**) est un coureur cycliste espagnol de la catégorie élite, titulaire d'une licence délivrée par la RFEC. Membre à l'époque des faits de l'équipe cycliste Euskaltel, il a participé à la course cycliste internationale sur route « Critérium du Dauphiné Libéré » qui s'est déroulée du 5 au 12 juin 2005.
4. A l'issue de l'étape du 11 juin 2005, Monsieur Landaluce a fait l'objet d'un contrôle antidopage. Au cours du prélèvement de l'échantillon, Monsieur Landaluce a indiqué avoir pris de la triamcinolone en infiltration le 21 mars 2005.
5. L'échantillon A prélevé sur Monsieur Landaluce a été analysé par le laboratoire français de dépistage du dopage de Châtenay-Malabry (le **LNDD**), laboratoire accrédité par l'Agence Mondiale Antidopage (l'**AMA**). Son rapport d'analyse du 17 juillet 2005 a révélé que « *l'analyse par spectrométrie de masse de rapports isotopiques indique une prise de Testostérone ou de l'un de ses précurseurs* ». Le 28 juillet 2005, le rapport d'analyse relatif à l'échantillon A a été transmis à la RFEC, afin que soit mise en œuvre une procédure disciplinaire, conformément à l'article 187 du RCAD.
6. Le 11 août 2005, Monsieur Landaluce a, par l'intermédiaire de la RFEC, sollicité une contre-analyse. Il a ensuite demandé que la contre-analyse qui était initialement prévue les 14 et 21 septembre 2005, soit reportée au 19 octobre 2005. Le 21 octobre 2005, la contre-analyse a confirmé la présence de testostérone de nature exogène dans l'échantillon B.

7. Par télécopie du 27 octobre 2005, l'UCI a transmis les résultats d'analyse de l'échantillon B à la RFEC et lui a demandé de poursuivre la procédure disciplinaire.
8. Le 5 mai 2006, la RFEC, par l'intermédiaire du Comité Nacional de Competición y Disciplina Deportiva (Comité national de compétition et discipline sportive / *CNCDD*), a jugé que les conditions dans lesquelles l'analyse avait été effectuée révélaient l'existence « *d'un processus incomplet pour ne pas être conforme à toutes les exigences légales applicables et, ainsi, ne pouvant pas garantir totalement le résultat* ». Le CNCDD a dès lors estimé que « *la maxime juridique « in dubio pro reo » [était] pleinement applicable au cas présent* », a classé l'affaire et acquitté Monsieur Landaluce.
9. Monsieur Landaluce n'a participé à aucune course cycliste entre le 24 juillet 2005 et le 15 mai 2006.

II. LA PROCÉDURE DEVANT LE TRIBUNAL ARBITRAL DU SPORT

A. LES DEMANDES ET REPONSES DES PARTIES

10. Par déclaration du 26 juin 2006, l'UCI a saisi le Tribunal Arbitral du Sport (le *TAS*).

Le 17 juillet 2006, l'UCI a déposé son mémoire d'appel demandant au TAS :

- « 1) *de réformer la décision du Comité national de compétition et discipline sportive de la RFEC ;*
- 2) *de condamner M. Landaluce Intxaurreaga à une suspension de 2 ans, conformément au RAD ;*
- 3) *de prononcer la disqualification de M. Landaluce Intxaurreaga des courses cyclistes auxquelles il a participé à partir du 11 juin 2005 et notamment de la course cycliste du « Critérium du Dauphiné Libéré 2005 », jusqu'au 29 juillet 2005 au moins ;*
- 4) *de condamner M. Landaluce Intxaurreaga et la Real Federacion Española de Ciclismo à payer à l'UCI un montant de CHF 1'000.- à titre de frais de gestion des résultats (art. 245.2 RAD) ;*
- 5) *de condamner M. Landaluce Intxaurreaga et la Real Federacion Española de Ciclismo, solidairement à rembourser à l'UCI l'émolument de CHF 500.- et à tous les autres frais, y compris une contribution aux frais de l'UCI ».*

11. Monsieur Landaluce a déposé sa réponse le 8 septembre 2006, aux termes de laquelle il demande au TAS de :

- se déclarer incompétent ;
- condamner l'UCI au paiement des frais générés par la procédure.

A titre subsidiaire, Monsieur Landaluce sollicite du TAS qu'il :

- rejette l'appel interjeté par l'UCI ;
- ne prononce aucune sanction à son encontre ;
- condamne l'UCI au paiement des frais.

A titre encore plus subsidiaire, Monsieur Landaluce fait valoir que toute sanction prononcée à son encontre devra être réduite de 9 mois et demi, période pendant laquelle il s'est abstenu de courir.

12. La RFEC a déposé sa réponse le 14 septembre 2006, faisant valoir en substance que :

- la décision de la CNCDD doit être confirmée ;
- l'UCI doit être déboutée de son appel ;
- l'UCI doit être condamnée aux dépens, en application de l'article 282 du RCAD.

B. L'AUDIENCE

13. L'audience a eu lieu le 11 octobre 2006, au siège du TAS à Lausanne (l'*Audience*), en présence des trois membres du Tribunal Arbitral (la *Formation*) et des avocats des parties.

14. La Formation a entendu les témoins et experts suivants :

- Pour l'UCI :
 - Docteur Martial Saugy, directeur du laboratoire suisse d'analyse du dopage, (*Dr Saugy*) ;
 - Professeur Jacques de Ceaurriz, directeur du LNDD (*Prof. de Ceaurriz*).
- Pour Monsieur Landaluce :

- Docteur Douwe de Boer, chercheur au Laboratoire de chimie clinique à l'Hôpital Universitaire de Maastricht et ancien directeur du Département dopage du Laboratoire d'analyses et de dopage de Lisbonne (*Dr de Boer*);
- Docteur Detlef Thieme, spécialiste en toxicologie médico-légale au sein du département de toxicologie médico-légale de l'Institut de médecine légale de Munich (*Dr Thieme*);
- Monsieur Ignacio Colomer Hernández, Professeur de droit à l'Université Carlos III de Madrid (*Prof. Colomer*), entendu par vidéoconférence.

C. S'AGISSANT DE LA PRODUCTION DES PIÈCES 43 ET 43 BIS PAR MONSIEUR LANDALUCE ET DE L'AUDITION DE MONSIEUR MIGUEL MADARIAGA

15. Le 22 septembre 2006, soit 14 jours après avoir déposé sa réponse, Monsieur Landaluce a déposé les pièces complémentaires 43 et 43 bis.
16. L'UCI s'étant opposée à la production desdites pièces le 25 septembre 2006, Monsieur Landaluce a indiqué, par télécopie du 2 octobre 2006, qu'il souhaitait faire entendre comme témoin Monsieur Miguel Madariaga (*Monsieur Madariaga*).
17. Par télécopie du 4 octobre 2006, l'UCI s'est opposée à l'audition de Monsieur Madariaga, la réponse de Monsieur Landaluce ne mentionnant aucunement l'audition de ce témoin.
18. Aux termes de l'article R56 du Code de l'arbitrage en matière de sport :

« Sauf accord contraire des parties ou décision contraire du Président de la formation commandée par des circonstances exceptionnelles, les parties ne sont pas admises à compléter leur argumentation, ni à produire de nouvelles pièces, ni à formuler de nouvelles offres de preuves après la soumission de la motivation d'appel et de la réponse ».
19. Lors de l'Audience, l'UCI a indiqué qu'elle ne donnerait son accord à l'audition de Monsieur Madariaga que si elle pouvait verser aux débats une nouvelle pièce reçue la veille. Le Président de la Formation a demandé que la pièce soit transmise à la RFEC et à Monsieur Landaluce afin que ceux-ci en prennent connaissance. Au vu de la pièce, Monsieur Landaluce a renoncé à faire entendre Monsieur Madariaga.
20. En l'absence de « *circonstances exceptionnelles* » au sens de l'article R56 du Code de l'arbitrage en matière de sport, le Président de la Formation a décidé de ne pas admettre

les nouvelles pièces et de ne pas procéder à l'audition du témoin.

III. S'AGISSANT DE LA COMPÉTENCE DU TAS

21. L'organisation de compétitions professionnelles internationales suppose une répartition claire des compétences entre les autorités nationales et internationales, d'une part, entre le secteur public et le secteur privé, d'autre part.
22. Il est des domaines, tel que le trafic de stupéfiants, pour lesquels chaque État exige, au nom de la souveraineté nationale, de contrôler lui-même tout comportement répréhensible sur son territoire, et refuse de laisser à des associations privées le soin de s'en charger, fût-ce par le biais d'une délégation de service public.
23. En revanche, la discipline en matière sportive, qui se traduit par la disqualification de l'athlète ou par l'interdiction qui lui est faite de participer à de futures compétitions, répond essentiellement à la volonté d'éliminer toute concurrence déloyale. C'est pourquoi elle est légitimement confiée à des autorités sportives.
24. Cela est d'autant plus vrai s'agissant de l'exercice d'un sport au niveau international, qui ne saurait obéir à une multiplicité de règles nationales potentiellement contradictoires.
25. Confier aux seules lois nationales le soin de régir les conditions dans lesquelles doivent se dérouler les compétitions internationales aboutirait à un système incohérent et inégalitaire, avec de surcroît le risque que les autorités nationales se livrent tôt ou tard à une course à la législation la moins répressive.
26. Pour pallier de tels inconvénients il suffit de s'assurer que la même discipline sportive, lorsqu'elle se déroule dans un cadre international, est soumise aux mêmes règles pour tous les concurrents.
27. Or, Monsieur Landaluce tente de faire accroire que la situation juridique en Espagne dicterait une solution différente. Il fait en effet valoir que le TAS ne serait pas compétent pour connaître de l'appel de l'UCI contre une décision du CNCDD et indique que le Comité Espagnol de Discipline Sportive du Conseil Supérieur des Sports Espagnols (le *CEDS*) serait seul compétent.
28. Au soutien de sa prétention, Monsieur Landaluce invoque un certain nombre de textes qui sont repris ci-après :

- L'article 6 des Statuts de l'UCI :
 - « 1. Les fédérations s'engagent, du fait de leur affiliation, à se conformer aux statuts et règlements de l'UCI ainsi qu'à toute décision prise conformément à ceux-ci. De même, elles s'engagent à faire respecter les statuts, règlements et décisions de l'UCI par toute personne concernée.
 - 2. Les règlements de l'UCI doivent être repris dans les règlements correspondants des fédérations.
 - 3. Les statuts et règlements des fédérations ne peuvent aller à l'encontre de ceux de l'UCI. En cas de divergence, seuls les statuts et les règlements de l'UCI seront appliqués. Les statuts et les règlements des fédérations doivent contenir la clause expresse qu'en cas de conflit avec les statuts ou règlements de l'UCI, seuls ces derniers seront appliqués.
 - 4. Les alinéas ci-dessus sont appliqués dans le respect des dispositions de droit impératif en vigueur dans le pays de la fédération concernée ».
- L'article 35 du Décret Royal 1835/1991 du 20 décembre 1991 relatif aux fédérations sportives espagnoles :
 - « Les questions suivantes ne pourront pas faire l'objet d'une conciliation ou d'un arbitrage : [...] »
 - b) Celles qui seront en relation avec le contrôle des substances et des méthodes prohibées dans le sport et la sécurité de la pratique sportive [...] ».
- L'article 90.2 des Statuts de la RFEC dans sa rédaction issue de la décision du 11 octobre 2004 :
 - « Les questions suivantes ne pourront pas faire l'objet d'une conciliation : [...] »
 - b) Celles qui seront en relation avec le contrôle des substances et des méthodes prohibées dans le sport et la sécurité de la pratique sportive [...] ».
- L'article 24 de la Constitution espagnole du 28 décembre 1978 :
 - « 1. Toute personne a le droit d'obtenir la protection effective des juges et des tribunaux pour exercer ses droits et ses intérêts légitimes sans, qu'en aucun cas, cette protection puisse lui être refusée.
 - 2. De même, toute personne a le droit d'aller devant le juge ordinaire déterminé préalablement par la loi, de se défendre et de se faire assister par un avocat, d'être informée de l'accusation portée contre elle, d'avoir un procès public sans délai indu et avec toutes les garanties, d'utiliser les preuves nécessaires à sa défense, de ne pas faire de déclaration contre elle-même, de ne pas s'avouer coupable et d'être présumée innocente ».
- L'article 91.1 des Statuts de la RFEC dans sa rédaction issue de la décision du 11 octobre 2004 :
 - « La déclaration de volonté irréfutable des parties au litige de se soumettre à la procédure de conciliation sera exigée. Pour cela, une convention

d'arbitrage sera souscrite par écrit et devra exprimer la renonciation à la voie judiciaire, l'obligation de se soumettre à la décision d'un ou de plusieurs arbitres et aux règles de procédure ».

- L'article 84.1 de la Loi 10/1990 du 15 octobre 1990 relative au Sport :
« Le Comité Espagnol de Discipline Sportive est l'organe national affecté organiquement au Conseil Supérieur des Sports qui, agissant indépendamment de celui-ci, tranche en dernier recours, par voie administrative, les litiges portant sur les questions disciplinaires sportives qui relèvent de son ressort ».
- L'article 10 des Statuts de la RFEC :
« 1. Sous la coordination et la tutelle du Conseil Supérieur des Sports, la RFEC exercera les fonctions publiques de nature administrative suivantes : [...]
f) Exercer l'autorité disciplinaire sportive, selon les termes établis par la Loi sur le Sport, ses dispositions particulières de développement et ses statuts et règlements ».
- L'article 59 du Décret Royal 1591/1992 du 23 décembre 1993 :
« Les compétences du Comité Espagnol de Discipline Sportive s'étendent :
a. A la connaissance et décision, par voie de recours, des prétentions formulées en ce qui concerne les actes des organes sportifs titulaires de l'autorité disciplinaire qui épuisent la voie sportive, selon la répartition des compétences établie par la Loi sur le Sport et par le présent décret royal ».

29. Monsieur Landaluce prétend en substance :

- que le recours à l'arbitrage serait interdit en matière de dopage en Espagne ;
- que la Constitution espagnole érigerait un droit inaliénable d'accès à la justice et aux tribunaux. Monsieur Landaluce indique qu'il ne saurait être privé de ce droit constitutionnel d'accès à la justice en n'étant autorisé à porter son appel que devant le TAS ;
- ne jamais avoir manifesté sa volonté de se soumettre à l'arbitrage du TAS et n'avoir signé aucune convention d'arbitrage. Monsieur Landaluce estime que le simple fait de disposer d'une licence de la RFEC ne saurait valoir acceptation de la compétence du TAS ;
- que la RFEC serait une autorité publique exerçant des fonctions publiques disciplinaires sous la tutelle d'un organisme public espagnol. Monsieur Landaluce estime, en conséquence, que les décisions de la RFEC devraient

faire l'objet d'un recours administratif devant le CEDS puis, le cas échéant, devant le juge administratif espagnol ;

- qu'en vertu de l'article 6 alinéa 4 des Statuts de l'UCI, la RFEC doit respecter la législation espagnole lorsqu'elle applique les normes de l'UCI ;
- que les articles 242 et 280 à 285 du RCAD, qui établissent la compétence exclusive du TAS pour connaître de l'appel dirigé contre les décisions des fédérations nationales seraient inapplicables conformément à l'article 6.4 des Statuts de l'UCI, dès lors que cette compétence exclusive violerait le droit espagnol ;
- que l'arrêt du Tribunal central de contentieux administratif n° 7 de Madrid du 8 juin 2006 rendu dans une affaire Santiago Perez Fernandez reconnaît la possibilité de former un recours hiérarchique contre les décisions du CNCDD devant le CEDS puis, le cas échéant, devant le juge administratif espagnol.

30. L'UCI estime, pour sa part, que le TAS est compétent et que le RCAD est applicable, en se fondant sur les textes suivants :

- L'article 1.1.001 du Règlement du sport cycliste de l'UCI :
« La licence est une pièce d'identité qui confirme l'engagement de son titulaire à respecter les statuts et règlements et qui l'autorise à participer aux événements cyclistes ».
- L'article 1.1.004 du Règlement du sport cycliste de l'UCI :
« Toute personne demandant une licence s'engage de ce fait à respecter les statuts et les règlements de l'UCI, des confédérations continentales de l'UCI et des fédérations membres de l'UCI et à participer aux manifestations cyclistes d'une manière sportive et loyale. Elle s'engage notamment à respecter les obligations visées à l'article 1.1.023.
Dès la demande de licence et pour autant que la licence est délivrée, le demandeur est responsable des infractions aux règlements qu'il commet et soumis à la juridiction des instances disciplinaires.
Tout licencié reste soumis à la juridiction des instances disciplinaires compétentes pour les faits commis alors qu'il était demandeur ou titulaire d'une licence, même si la procédure est engagée ou se poursuit après le moment où l'intéressé n'a plus de licence ».
- L'article 1.1.023 du Règlement du sport cycliste de l'UCI :
« [...] 2. Je m'engage à respecter les statuts et règlements de l'Union Cycliste Internationale, de ses confédérations continentales et de ses fédérations nationales.

Je déclare avoir lu ou avoir eu la possibilité de prendre connaissance de ces statuts et règlements.

Je participerai aux compétitions ou manifestations cyclistes d'une manière sportive et loyale.

Je me soumettrai aux sanctions prononcées à mon égard et porterai les appels et litiges devant les instances prévues aux règlements. J'accepte le Tribunal Arbitral du Sport (TAS) comme seule instance d'appel compétente dans les cas et suivant les modalités prévues par les règlements.

J'accepte que le TAS se prononce en dernière instance et que ses décisions seront définitives et sans appel. Sous ces réserves, je soumettrai tout litige éventuel avec l'UCI exclusivement aux tribunaux du siège de l'UCI.

3. J'accepte de me soumettre à et être lié par le règlement antidopage de l'UCI, les clauses du Code Mondial Antidopage et ses Standards internationaux auxquels le règlement antidopage de l'UCI fait référence ainsi que les règlements antidopage des autres instances compétentes suivant les règlements de l'UCI et le Code Mondial Antidopage, pour autant qu'ils soient conformes à ce Code. [...] ».

- L'article 5 des dispositions préliminaires du Règlement du sport cycliste de l'UCI :

« La participation à une épreuve cycliste, à quelque titre que ce soit, vaut acceptation de toutes les dispositions qui y trouvent application ».

31. L'UCI indique, en substance, qu'il ressort de la lecture combinée des articles précités que :

- les licenciés des fédérations membres de l'UCI sont soumis au RCAD ;
- toute personne qui demande une licence s'engage à respecter le RCAD et s'engage notamment à se soumettre aux contrôles antidopage et à la compétence du TAS en dernier ressort.

32. Au soutien de sa prétention, l'UCI rappelle que la décision du CNCDD du 5 mai 2006 dont il est fait appel a été rendue en application du RCAD.

33. En outre, lors de l'Audience, l'UCI a fait valoir que :

- le TAS devrait apprécier la compétence et l'arbitrabilité des litiges selon la loi fédérale suisse sur le droit international privé (**LDIP**) aux termes de laquelle (i) le dopage est arbitral, et (ii) les clauses d'arbitrage par référence sont valables (article 178 de la LDIP) ;
- selon la jurisprudence du TAS, l'existence d'une loi nationale n'empêcherait pas l'application de la réglementation de la fédération internationale (TAS 2005/A/872, sentence du 30 janvier 2006, UCI / Federico Muñoz Fernandez et Federación Colombiana De Ciclismo) ;

- la législation espagnole invoquée par Monsieur Landaluce n'aurait vocation à s'appliquer qu'en Espagne, comme le révéleraient :
 - (i) l'article 1.3° du Décret Royal 1835/1991 du 20 décembre 1991 sur les fédérations sportives espagnoles, aux termes duquel le champ de compétence des fédérations sportives espagnoles se limiterait au territoire national ;
 - (ii) le préambule de la Loi 10/1990 du 15 octobre 1990 sur le sport, selon lequel l'objectif de la loi serait de définir le cadre juridique applicable à la pratique sportive au sein du territoire espagnol.
 - l'article 7 du Décret Royal 255/1996 du 16 février 1996, aux termes duquel les sanctions imposées en application des règles antidopage d'une quelconque fédération, que celle-ci soit nationale, internationale ou autonome, produisent leurs effets sur l'ensemble du territoire espagnol, révélerait nécessairement que des sanctions peuvent être imposées par d'autres fédérations que la RFEC et produire leurs effets en Espagne ;
 - n'admettre comme seule voie de recours contre les décisions du CNCDD l'appel devant le CESD équivaldrait à priver l'UCI de tout droit de regard sur les décisions émanant de la fédération nationale, dans la mesure où l'UCI ne serait pas habilitée à former appel devant la juridiction espagnole.
34. Dans ses écritures et lors de l'Audience, la RFEC a indiqué se rallier à l'interprétation faite par l'UCI, s'agissant de la compétence du TAS. La RFEC a par ailleurs indiqué qu'elle était un établissement privé « à deux casquettes » exerçant, selon les cas, des missions d'ordre public ou d'ordre privé. La RFEC a précisé que, dans le cadre de compétitions internationales, comme au cas particulier, elle exerçait une mission d'ordre privé.
35. Lors de l'Audience, le Prof. Colomer a fait les observations suivantes :
- l'octroi d'une licence par la RFEC serait constitutif d'un acte administratif ;
 - le pouvoir de sanction de la RFEC interviendrait dans le cadre de l'exercice d'une fonction publique ;

- le TAS ne serait pas compétent car la sanction imposée par le CNCDD serait un acte administratif ;
 - l'interdiction du recours à l'arbitrage en matière de dopage serait impérative pour les parties, qui ne sauraient y déroger ;
 - la Constitution espagnole prévaudrait sur tout traité international ;
 - tout décret contraire à la Constitution espagnole serait anticonstitutionnel ;
 - l'article 7 du Décret Royal 255/1996 du 16 février 1996 serait anti-constitutionnel.
36. Consciente du fait que le présent litige illustre la tension qui peut exister entre la loi nationale d'un athlète et le règlement de la fédération internationale auquel celui-ci est soumis, la Formation rappelle que l'UCI est l'association des fédérations nationales du cyclisme qui a pour but la direction, le développement, la réglementation, le contrôle et la discipline du cyclisme international, notamment en matière de dopage. Monsieur Landaluce est, quant à lui, un cycliste professionnel de la catégorie élite, titulaire d'une licence aux termes de laquelle il a accepté de se soumettre aux règles de l'UCI.
37. Certes, la demande de licence de Monsieur Landaluce révèle que le modèle de demande de licence utilisé par la RFEC n'est pas conforme au règlement de l'UCI. Toutefois, les articles 2 et 3 de la demande de licence signée par Monsieur Landaluce indiquent que son détenteur s'engage à respecter la législation espagnole en vigueur, les Statuts de l'UCI ainsi que de ses confédérations, et qu'il accepte de se soumettre aux contrôles antidopage dans les conditions prévues à l'article 1.1.023 du Règlement du sport cycliste de l'UCI ainsi qu'à la compétence du TAS qui y est explicitement prévue. La RFEC n'a d'ailleurs pas manqué d'indiquer, lors de l'Audience, que le fait de lui demander une licence valait acceptation de la compétence du TAS, même en l'absence d'une clause expresse à cet effet. La Formation considère qu'en demandant sa licence à la RFEC, Monsieur Landaluce s'est soumis à la compétence du TAS, ainsi qu'aux règlements de l'UCI.
38. D'aucuns pourraient penser qu'il aurait été préférable que la demande de licence mentionne expressément la soumission des parties à l'arbitrage du TAS. A cet égard, la Formation souligne que les coureurs d'élite ne sont pas des profanes, contrairement aux consommateurs, mais des sportifs avertis qui ont sans le moindre doute connaissance de

l'existence du TAS et de sa compétence pour connaître des affaires de dopage. Dès lors, la compétence du TAS telle que prévue à l'article 1.1.023 du Règlement du sport cycliste ne saurait en aucun cas constituer une surprise pour la personne qui formule une demande de licence. Exiger qu'en sus des éléments rappelés au paragraphe 37 ci-dessus, la demande de licence mentionne expressément la compétence du TAS pour que celui-ci soit compétent, serait un excès de formalisme et une exigence non requise par la jurisprudence du Tribunal fédéral suisse.

39. L'argumentation de Monsieur Landaluce tendant à faire valoir que l'article 6 alinéa 4 des Statuts de l'UCI enjoindrait à la RFEC d'appliquer la loi espagnole et d'interdire le recours à l'arbitrage du TAS n'emporte guère la conviction de la Formation. En effet, l'article 6 des Statuts de l'UCI s'adresse aux seules fédérations nationales. Les trois premiers alinéas de cet article mettent à la charge de ces fédérations une obligation d'harmoniser leurs règles en reprenant les règlements de l'UCI. Le quatrième alinéa de l'article 6 des Statuts de l'UCI, indique simplement que cette harmonisation doit tenir compte d'éventuelles dispositions impératives applicables dans le pays de la fédération concernée. En conséquence, l'article 6 alinéa 4 des Statuts de l'UCI renvoie expressément aux trois paragraphes qui le précèdent et ne saurait être détaché de son contexte. L'article 6 des Statuts de l'UCI ne s'adresse donc qu'aux fédérations nationales, en vue de leur indiquer la démarche à suivre afin d'harmoniser leur droit, et ne saurait nullement être invoqué par un cycliste afin de se soustraire à l'application des règlements de l'UCI et, ce faisant, à la compétence du TAS.
40. Au demeurant, aucune disposition de la loi espagnole n'exclut le recours à l'arbitrage. Ce n'est certainement pas le cas de l'article 24 de la Constitution espagnole. Il suffit pour s'en convaincre de comparer la portée de ce texte à celle de l'article 6 alinéa 1 de la Convention européenne des droits de l'homme (la **CEDH**) qui prévoit que « *toute personne a droit à ce que sa cause soit entendue [...] par un tribunal indépendant et impartial, établi par la loi* ». Or, la Commission européenne des droits de l'homme a jugé dans une affaire X. / RFA du 5 mars 1962, que l'insertion d'une clause compromissoire dans un contrat valait renonciation au bénéfice de la CEDH et qu'aucune stipulation de la CEDH n'interdisait une telle renonciation. Sauf preuve du contraire, l'article 24 de la Constitution espagnole, tout comme l'article 6 alinéa 1 de la CEDH, n'interdit nullement le recours à l'arbitrage. En effet, la compétence du TAS ne

prive pas Monsieur Landaluce de son droit d'accès à la justice tel que prévu par la Constitution espagnole, dès lors qu'en matière internationale, le recours à l'arbitrage est une modalité d'exercice de ce droit.

41. La Formation considère en définitive, que les dispositions espagnoles invoquées par Monsieur Landaluce n'ont vocation à s'appliquer que dans le cadre de compétitions cyclistes nationales, et ne sauraient faire obstacle ni à l'application des règlements de l'UCI, ni à la compétence du TAS. En juger autrement conduirait à une véritable course à la législation nationale la plus clémente.
42. Il est en effet impératif que les fédérations sportives internationales, telles que l'UCI, aient un droit de regard sur les décisions des fédérations nationales en matière de dopage. Ce droit de regard de l'UCI, qui se matérialise par la possibilité de former un appel à l'encontre des décisions des fédérations nationales devant le TAS, a pour objet de pallier le risque que la compétition internationale ne soit faussée par une fédération nationale qui se garderait de sanctionner ses membres.
43. Par conséquent, l'argument de Monsieur Landaluce tendant à faire valoir que la seule voie de recours contre les décisions du CNCDD serait un appel devant le CESD ne saurait emporter l'adhésion de la Formation.
44. De même, la contestation par Monsieur Landaluce de la compétence du TAS au motif que la réglementation antidopage serait confiée à une autorité publique porte à faux. Il ressort en effet de la jurisprudence du TAS que le pouvoir des fédérations internationales, telles que l'UCI, s'exerce quand bien même le contrôle et la sanction du dopage seraient confiés, comme au cas particulier, à une autorité publique.
45. Le pouvoir des fédérations internationales a pour objet d'éliminer toute concurrence déloyale et toute course à la législation la plus clémente. Elle tend à soumettre tous les athlètes à un traitement égalitaire, en veillant à ce que certaines fédérations nationales ne fassent pas preuve de passivité face aux manquements commis par leurs sportifs nationaux. C'est ainsi que dans une affaire de dopage de nageurs en 1997, le TAS a reconnu comme nécessité impérieuse que les fédérations internationales aient la possibilité de revoir les décisions des fédérations nationales dans les cas de dopage. Il s'agit de prévenir le risque que les compétitions internationales ne soient faussées, en raison des sanctions trop clémentes que pourrait être tentée de prononcer une fédération nationale (TAS 96/156, sentence du 10 octobre 1997, F. / FINA).

46. Par la suite, une autre formation du TAS a eu l'occasion d'étendre cette jurisprudence aux sanctions prononcées par les autorités publiques nationales, dans une sentence B. / Fédération Internationale du Judo du 17 mars 1999 (TAS 98/214, sentence du 17 mars 1999, B. / Fédération Internationale de Judo). Il s'agissait, en l'espèce, d'un contrôle de dopage positif sanctionné par une suspension prononcée par un arrêté du Ministre des Sports français. En effet, une loi française de 1989 donnait audit Ministre le pouvoir de substituer sa décision à toute mesure d'interdiction prise par des fédérations sportives nationales. Au cas particulier, la Fédération française avait prononcé une sanction de deux ans de suspension, dont une avec sursis, à laquelle l'arrêté ministériel avait substitué une simple suspension d'un an. Or, cette dernière sanction n'était pas conforme aux règlements de la Fédération Internationale de Judo (*FIJ*) qui a donc porté l'affaire devant le TAS. Ce dernier a prononcé une suspension de 15 mois.
47. A l'occasion de cette sentence, les arbitres avaient évoqué le problème qui est au cœur du présent litige :

« La formation est d'avis que la latitude accordée par cette jurisprudence aux fédérations internationales doit être étendue aux cas où la procédure de contrôle et la sanction de dopage ne sont pas diligentées par une fédération nationale, conformément à une réglementation sportive, mais par une autorité publique, en application d'une loi nationale, comme en l'espèce, ou, le cas échéant, sur la base d'une convention internationale. »

Le pouvoir d'extension au niveau international des décisions nationales relatives au dopage, quelle que soit l'autorité qui les prononce, se justifie non seulement par le souci de prévenir le risque de voir certaines fédérations ou des organismes gouvernementaux se livrer à une concurrence déloyale des plus malsaines, en omettant de sanctionner leurs sportifs de manière aussi rigoureuse et sévère que d'autres fédérations et / ou que leur fédération internationale, mais aussi par l'objectif que chaque fédération internationale doit chercher à atteindre, à savoir faire respecter un traitement égal et cohérent à tous les pratiquants du même sport ».

48. En conséquence, les dispositions du droit espagnol auxquelles il est fait référence ne permettent pas de conclure à l'incompétence du TAS. C'est ce que le TAS a constaté à différentes reprises, notamment dans le domaine du cyclisme dans l'affaire Muñoz (TAS 2005/A/872, sentence du 30 janvier 2006, UCI / Federico Muñoz Fernandez et Federación Colombiana De Ciclismo), à l'occasion de laquelle la conclusion suivante a été formulée :

“The panel is prepared to accept that as a matter of Colombian Law it was possible for Mr Muñoz to appeal to the General Disciplinary Committee of the Colombian National Olympic Committee. However, to do so was a breach of his contract with the

UCI. At best, the decision of the General Disciplinary Committee could only have an effect within Colombia. It would not entitle Mr Muñoz to participate in cycle races organized under the auspices of the UCI, or to avoid the UCI's disciplinary code”.

49. L'autorité des États et l'autorité sportive internationale ne sont pas en concurrence ; au contraire, leurs rôles sont complémentaires. L'autorité étatique se borne à contrôler la conduite de ses justiciables, tandis que la fédération internationale gère les compétitions qui relèvent de son ressort. Un même comportement peut être sanctionné pénalement dans un lieu donné, sans pour autant entraîner une sanction du cycliste au niveau international. De même, un comportement peut ne pas être sanctionné pénalement tout en étant néanmoins susceptible de générer une exclusion des concours sportifs car il porte atteinte à la loyauté de la compétition.
50. Cette complémentarité entre autorité sportive étatique et internationale peut revêtir une forme particulière lorsqu'une autorité publique se substitue à la fédération nationale pour décider des sanctions – comme ce fut le cas dans l'affaire de la FIJ précitée, ou comme au cas présent. La souveraineté nationale, telle qu'elle s'exprime à l'occasion d'une mesure disciplinaire sportive rendue par une autorité nationale, n'a, en principe, vocation à s'appliquer que sur le seul territoire national. La décision nationale peut toutefois être remplacée par une décision de l'autorité internationale – le TAS – pour que soit assurée la nécessaire uniformité du droit. Certes, il est théoriquement concevable que l'État impose ses décisions nationales jusque dans les compétitions internationales se déroulant sur son territoire au mépris de l'autorité internationale. Un tel comportement irait cependant à l'encontre de tous les efforts tendant à lutter contre le dopage au niveau international, et pourrait conduire à l'exclusion de l'État concerné de l'organisation des compétitions internationales. Il serait surprenant qu'un État souhaite se placer dans une telle situation, et rien dans les textes invoqués dans la présente affaire ne laisse à penser que telle serait la position adoptée par l'Espagne. Bien au contraire, le préambule du Décret Royal 255/1996 du 16 février 1996 reflète clairement que l'Espagne se soucie de la conformité de ses normes avec les normes internationales :
« En application de l'article 76.1.d) de la Loi sur le Sport et en accord avec les critères posés par les normes sportives internationales, le présent Décret Royal identifie les comportements constitutifs d'infractions aux règles du dopage et établit les sanctions y relatives [...] ».
51. Loin de venir au soutien de la prétention de Monsieur Landaluce, le Décret Royal 255/1996 du 16 février 1996 qu'il invoque, ne fait que confirmer le raisonnement qui a été développé ci-avant. En effet, l'article 7 de ce Décret reconnaît explicitement que les

sanctions prononcées par une fédération internationale produisent leurs effets sur l'ensemble du territoire espagnol. Le contraire aurait été pour le moins surprenant.

52. Aux vues de ce qui précède, la Formation conclut qu'elle est compétente pour connaître du présent litige, conformément aux articles 280 à 291 du RCAD.
53. Cela n'est d'ailleurs pas contesté par la RFEC qui a, tout au long de la procédure, reconnu la compétence du TAS et l'applicabilité du RCAD, auquel il était expressément fait référence dans la décision du CNCDD du 5 mai 2006, objet du présent recours.

IV. S'AGISSANT DE LA RECEVABILITÉ DE L'APPEL

54. L'article 285 du RCAD dispose que la déclaration d'appel de l'UCI doit être soumise au TAS dans un délai d'un mois à compter de la réception du dossier complet de l'instance d'audition de la fédération nationale. Toutefois, lorsque l'UCI n'a pas demandé le dossier dans les 15 jours suivant la réception de la décision, comme le prévoit l'article 247 du RCAD, le délai d'appel est d'un mois à compter de la réception de la décision complète.
55. Au cas particulier, l'UCI a reçu la décision du CNCDD le 9 mai 2006 et a demandé le dossier complet le 11 mai 2006. Le dossier complet a été reçu par l'UCI le 26 mai 2006. La déclaration d'appel ayant été envoyée le 26 juin 2006, l'appel a été formé dans les délais.

V. S'AGISSANT DU FOND

A. PRINCIPES GÉNÉRAUX

56. Aux termes de l'article 16 du RCAD :

« La charge de la preuve incombera à l'UCI et à ses fédérations nationales qui devront établir l'existence de la violation d'une règle antidopage. Le degré de preuve établira si l'UCI ou ses fédérations nationales ont satisfait à la charge de la preuve à la satisfaction de l'instance d'audition qui appréciera le sérieux de l'allégation. Le degré de preuve, dans tous les cas, devra être plus important qu'un juste équilibre des probabilités, mais moins qu'une preuve au-delà d'un doute raisonnable. Lorsque le présent règlement antidopage confie au coureur, ou à une autre personne présumée avoir commis une violation des règles antidopage, la charge de renverser une présomption ou d'établir des circonstances ou des faits spécifiques, le degré de preuve devra être fondé sur un juste équilibre de probabilités ».

57. S'agissant du mode d'établissement des faits et présomptions, l'article 18 du RCAD prévoit que :

« Les laboratoires accrédités par l'AMA ou approuvés d'une autre manière par l'AMA sont présumés avoir effectué l'analyse des échantillons et respecté les procédures de la chaîne de sécurité conformément aux standards internationaux pour les laboratoires. Le coureur peut renverser cette présomption en démontrant qu'un écart est survenu par rapport aux standards internationaux.

Si le coureur parvient à renverser la présomption en démontrant qu'un écart est survenu par rapport aux standards internationaux pour les laboratoires, il incombera alors à l'UCI ou à la fédération nationale de démontrer que cet écart n'a pas pu être à l'origine du résultat d'analyse anormal ».

En d'autres termes, il existe une présomption réfragable selon laquelle les laboratoires accrédités par l'AMA ont effectué les analyses dans les règles de l'art, conformément au standard international applicable aux laboratoires (le *SIL*). Dans l'hypothèse où le coureur démontrerait l'existence d'un écart par rapport au *SIL*, il incomberait alors à l'UCI de démontrer que cet écart n'est pas à l'origine du résultat d'analyse anormal. Il convient donc d'appliquer ces règles afin de déterminer si Monsieur Landaluce établit la survenance d'écarts et dans l'affirmative, si l'UCI est en mesure de démontrer que l'écart invoqué n'est pas susceptible d'avoir donné lieu au résultat anormal.

58. Aux termes de l'article 15.1 du RCAD :

« Sont considérées comme violations des règles antidopage:

1. La présence d'une substance interdite, de ses métabolites ou marqueurs dans un prélèvement corporel d'un coureur.

1.1. Il incombe personnellement à chaque coureur de s'assurer qu'aucune substance interdite ne pénètre dans son organisme. Les coureurs sont responsables de toute substance interdite, de ses métabolites ou marqueurs dont la présence est décelée dans leurs prélèvements corporels. Par conséquent, il n'est pas nécessaire de faire la preuve de l'intention, de la faute, de la négligence ou de l'usage conscient de la part du coureur pour établir une violation des règles antidopage en vertu de l'article 15.1 ».

59. La substance testostérone est un stéroïde anabolisant androgène endogène, substance interdite qui figure sur la liste des interdictions 2005 sous la classe S1.1.b. La liste des interdictions prévoit que :

« Dans le cadre d'une substance interdite (selon la liste ci-dessus) pouvant être produite naturellement par le corps, un échantillon sera considéré comme contenant cette substance interdite si la concentration de la substance interdite ou de ses métabolites ou de ses marqueurs et/ou tout autre rapport pertinent dans l'échantillon du sportif s'écarte suffisamment des valeurs normales trouvées chez l'homme pour qu'une production endogène normale soit improbable. Un échantillon ne sera pas considéré comme contenant une substance interdite si le sportif prouve que la concentration de substance interdite ou de ses métabolites ou de ses marqueurs et/ou tout autre rapport pertinent dans l'échantillon du sportif est attribuable à un état physiologique ou pathologique. Dans tous les cas, et quelle que soit la concentration, le laboratoire rendra un résultat d'analyse anormal si, en se basant sur une méthode d'analyse fiable, il peut démontrer que la substance interdite est d'origine exogène.

Si le résultat de laboratoire n'est pas concluant et qu'aucune concentration décrite au paragraphe ci-dessus n'est mesurée, l'organisation antidopage responsable effectuera une investigation plus approfondie s'il existe de sérieuses indications, telles que la comparaison avec des profils stéroïdiens de référence, d'un possible usage d'une substance interdite.

Si le laboratoire a rendu un rapport T/E supérieur à quatre (4) pour un (1) dans l'urine, une investigation complémentaire est obligatoire afin de déterminer si le rapport est dû à un état physiologique ou pathologique, sauf si le laboratoire rapporte un résultat d'analyse anormal basé sur une méthode d'analyse fiable, démontrant que la substance interdite est d'origine exogène ».

B. APPLICATION DES PRINCIPES GÉNÉRAUX AU CAS PARTICULIER

60. Au cas particulier, le LNDD a utilisé la méthode d'analyse GC/C/IRMS, analyse par spectrométrie de masse du rapport isotopique. Le rapport d'analyse du LNDD a révélé la présence de testostérone de nature exogène. L'échantillon A présente un ratio T/E de 9,2, supérieur à la limite de 4 établie par l'AMA. Le rapport d'analyse du LNDD relatif à l'échantillon B confirme le résultat de l'analyse de l'échantillon A.
61. Le LNDD ayant effectué des analyses dont le résultat est positif, il appartient à Monsieur Landaluce de démontrer qu'un écart est survenu par rapport au SIL pour renverser la présomption selon laquelle ces analyses ont été réalisées dans les règles de l'art. Comme l'a rappelé à juste titre l'UCI au cours de l'Audience, Monsieur Landaluce ne pourrait se contenter d'indiquer que *« something could potentially be wrong »*, mais doit bien rapporter la preuve d'une violation du SIL.

62. Pour ce faire, Monsieur Landaluce conteste la validité des analyses pratiquées par le LNDD, invoquant des manquements et des irrégularités commis lors du processus d'analyse. Il fait valoir que ces irrégularités rendaient « *invalides* » les résultats de l'analyse effectuée et a indiqué que « *ces résultats ne seront jamais considérés comme preuve de la commission d'une faute pouvant être sanctionnée* ».
63. A cette fin, Monsieur Landaluce souligne qu'il fait siennes les observations du Dr de Boer et de Madame Luisa Lurueña Sánchez, pharmacienne et spécialiste en analyse et contrôle des médicaments et drogues.
64. Madame Luisa Lurueña Sánchez observe que :
- « Avec la documentation remise nous pouvons dire que celle-ci est insuffisante pour démontrer l'abus de testostérone ou un de ses précurseurs.
Etant donnée la mauvaise, faible et inconsistante documentation analytique réalisée apportée pour démontrer l'abus de testostérone ou analogues dans cet échantillon, on considère que l'innocence du sportif peut être défendue ».*
65. Au soutien de sa prétention, Monsieur Landaluce a également versé aux débats de nombreux rapports élaborés par le Dr de Boer qui estime que plusieurs irrégularités auraient été commises par le LNDD et souligne que le SIL n'aurait pas été respecté. Dans son rapport du 12 mars 2006, le Dr de Boer observe notamment que :
- « Le laboratoire AMA de Châtenay-Malabry n'a pas fait d'erreur concernant l'analyse chimique, mais il n'a pas respecté, sous divers aspects, les normes internationales pour les laboratoires d'analyse (ISL, International Standards for Laboratories) de l'AMA. Ainsi, plusieurs non-conformités se sont produites, ce qui, entre autres, a abouti au fait que l'analyse des échantillons « A » et « B » était loin d'être complète ».*
66. Monsieur Landaluce invoque six écarts qui auraient été commis par le laboratoire par rapport aux normes du SIL. Quatre des manquements allégués ont trait à l'appréciation scientifique qui a été faite par le laboratoire, tandis que les deux autres sont relatifs à la procédure mise en œuvre par lui. La Formation se doit d'examiner les prétendues irrégularités invoquées par Monsieur Landaluce afin de déterminer si le LNDD s'est conformé au SIL.

1. S'agissant des manquements allégués ayant trait à l'appréciation scientifique par le LNDD

- a) L'argument selon lequel le dossier ne permettrait pas à un autre analyste d'évaluer les analyses réalisées et d'en interpréter les données (point 5.2.6.1 du SIL)*

67. Aux termes du point 5.2.6.1 du SIL :

«Le Laboratoire doit disposer de procédures documentées assurant la tenue coordonnée d'un dossier relatif à chaque Échantillon analysé. Dans le cas d'un Résultat d'analyse anormal, ce dossier doit comprendre les données justifiant les conclusions présentées (voir Document Technique "Documentation du Laboratoire"). En règle générale, le dossier doit être tenu de telle sorte que, en l'absence de l'analyste, un autre analyste compétent puisse évaluer les analyses réalisées et en interpréter les données ».

68. Le Dr de Boer a déclaré qu'il n'avait pas pu évaluer différents aspects des analyses en raison d'un manque d'information et a indiqué que les rapports relatifs aux échantillons A et B ne contenaient pas les informations permettant d'identifier les stéroïdes impliqués.

69. Le Dr Saugy a, pour sa part, indiqué que les informations permettaient d'identifier les stéroïdes impliqués. En effet, dans sa déclaration du 14 juillet 2006, le Dr Saugy a indiqué qu' *« après lecture attentive et raisonnable des paquets de documentation, j'estime que tous les aspects permettant de faire une évaluation du dossier sont présents dans celui-ci ».*

70. La Formation constate l'existence d'un désaccord entre les experts. Tandis que le Dr Saugy estime que le dossier permettait d'identifier les stéroïdes impliqués, le Dr de Boer considère quant à lui que les éléments dont il disposait étaient insuffisants. Les arbitres considèrent que le témoignage du Dr Saugy est plausible et que la démonstration faite par le Dr de Boer ne parvient pas à invalider son analyse.

71. En conséquence, la Formation estime que Monsieur Landaluce n'a pas démontré l'existence d'une violation du point 5.2.6.1 du SIL et qu'il n'est donc pas parvenu à renverser la présomption selon laquelle l'analyse du LNDD avait été réalisée dans les règles de l'art, telles qu'elles résultent du point 5.2.6.1 du SIL.

- b) *L'argument selon lequel la substance analysée serait une substance à seuil et que l'incertitude de 0,8 adoptée par le LNDD serait insuffisante (point 5.4.4.1.3 du SIL)*

72. Aux termes du point 5.4.4.1.3 du SIL :

« Le Laboratoire sera tenu d'atteindre, tant pour les Substances sans seuil que pour les Substances à seuil, la Limite Minimale de Performance Requise définie pour la détection et l'identification de la substance ou pour la démonstration de sa présence au-delà du seuil toléré (si nécessaire) ».

73. Le Dr de Boer estime que la valeur de l'incertitude de 0,8 présentée par le LNDD serait insuffisante et devrait être de 1,35. Il indique par ailleurs que le fait qu'un indice d'incertitude ait été donné démontrerait que le LNDD aurait considéré être en présence d'une substance à seuil dans la mesure où l'incertitude ne serait prise en compte que pour les substances à seuil. Le Dr de Boer conclut à l'existence d'un écart par rapport au point 5.4.4.1.3 du SIL.

74. Le Prof. de Ceaurriz et le Dr Saugy estiment quant à eux que cette valeur, utilisée par de nombreux laboratoires, serait conforme au point 5.4.4.1.3 du SIL. Dans sa déclaration du 14 juillet 2006, le Dr Saugy considère qu'il ne s'agit pas d'une mesure d'une substance à seuil mais d'une méthode de confirmation basée sur des mesures quantitatives, dont le but est de démontrer l'origine qualitative du produit ingéré.

75. L'UCI fait valoir qu'il ne s'agit pas d'une substance à seuil dans la mesure où la simple présence de testostérone exogène suffit. L'analyse isotopique viserait uniquement à démontrer la nature exogène du produit, sans se préoccuper de sa quantité.

76. Au soutien de son allégation, l'UCI se réfère au point 5.4.4.3 du SIL qui indique que :

« Dans la plupart des cas, l'identification d'une substance interdite ou des métabolite(s) ou marqueur(s) associés suffit pour que soit déclaré un résultat d'analyse anormal. La notion d'incertitude quantitative définie dans l'ISA/CEI 17025 n'est donc pas applicable ici. [...] »

Dans le cas des substances à seuil, il faut considérer à la fois l'incertitude sur l'identification et l'incertitude sur la démonstration de la présence de la substance à concentration supérieure au seuil ».

77. Dans sa déclaration du 14 juillet 2006, le Dr Saugy observe qu'au demeurant, le document technique TD2004 EAAS de l'AMA indiquerait que le résultat démontre l'administration d'un stéroïde exogène lorsque la valeur du métabolite diffère significativement de 3‰ ou plus de la valeur de la référence endogène utilisée.

Le Dr Saugy déclare qu'au cas particulier, l'analyse aurait révélé, tant pour l'échantillon A que pour l'échantillon B, une différence significativement supérieure à 3 ‰, à savoir 4,85 ‰ pour l'échantillon A et 4,76 ‰ pour l'échantillon B, entre la référence endogène et le métabolite retrouvé dans la testostérone.

78. La Formation constate qu'il n'existe en la matière aucune méthode précise et que les experts présents lors de l'Audience ne se sont pas accordés sur une valeur d'incertitude à prendre en compte pour l'analyse isotopique.
79. La Formation estime que Monsieur Landaluce n'a pas renversé la présomption selon laquelle le LNDD s'est conformé aux règles de l'art. En effet, les experts cités par Monsieur Landaluce, s'ils ont démontré leur désaccord avec la méthode de calcul adoptée par le LNDD, n'ont pas pour autant renversé la présomption selon laquelle les analyses se sont conformées au point 5.4.4.1.3 du SIL. La Formation estime donc que Monsieur Landaluce n'a pas rapporté la preuve d'un écart par rapport au point 5.4.4.1.3 du SIL.

c) L'argument selon lequel les informations sollicitées n'auraient pas été remises au cycliste ni à son expert (point 5.4.7.3 du SIL et des documents techniques TD2004EAAS et TD2003IDCR)

80. Monsieur Landaluce fait valoir qu'il n'aurait pas reçu les informations sollicitées à plusieurs reprises, tant par lui que par le Dr de Boer, qui auraient permis de procéder à l'évaluation de l'analyse effectuée par le LNDD.
81. L'UCI a indiqué qu'un courrier de la RFEC du 22 novembre 2005 démontrerait que Monsieur Landaluce a reçu l'intégralité des documents relatifs à l'analyse des échantillons A et B. L'UCI a également fait valoir qu'un courrier aurait été envoyé directement par le LNDD à la RFEC contenant les informations requises. Ce courrier aurait bien été reçu par la RFEC qui aurait tamponné cette correspondance, bien que la décision du CNCDD indique qu'aucune réponse de la LNDD n'aurait été reçue.
82. Par ailleurs, le Dr de Boer indique avoir reçu le 29 août 2006 un document contenant l'évaluation des temps de rétention concernant l'identification des stéroïdes impliqués dans l'analyse de l'échantillon B. Il observe toutefois qu'aucune information ne lui aurait été transmise s'agissant des données de masse spectrale et d'identification des stéroïdes impliqués dans l'analyse de l'échantillon A. Le Dr de Boer estime en

conséquence qu'il existerait un écart par rapport au point 5.4.7.3 du SIL et aux documents techniques TD2004EAAS et TD2003IDCR.

83. La Formation constate une nouvelle fois l'existence d'une divergence d'opinion entre les experts présents lors de l'Audience. Le Dr Saugy indique en effet que les informations nécessaires à l'identification de ces produits auraient été fournies par le LNDD. Cette analyse qui émane d'un expert jouissant d'une expérience non négligeable dans ce domaine est tout à fait plausible. Par conséquent, la Formation considère que Monsieur Landaluce n'a pas renversé la présomption selon laquelle le LNDD se serait conformé au point 5.4.7.3 du SIL et aux documents techniques TD2004EAAS et TD2003IDCR.

d) Les arguments selon lesquels les valeurs ne diffèreraient pas de manière significative de trois unités delta ou plus et qu' il aurait fallu analyser trois aliquotes (document technique TD2004EAAS)

84. Aux termes du document technique TD2004EAAS :

« Les résultats seront rapportés comme étant cohérents avec l'administration d'un stéroïde, lorsque la valeur 13C/12C mesurée pour le(s) métabolite(s) diffère de manière significative, à savoir d'au moins 3 unités delta, du stéroïde de référence urinaire sélectionné. Dans certains Echantillons, la mesure de la valeur 13C/12C du/des stéroïde(s) de référence sélectionné(s) peut ne pas être possible du fait de concentration(s) basse(s). Les résultats de telles analyses seront rapportés comme « non concluants », sauf si le rapport mesuré du (des) métabolite(s) est inférieur à - 28 ‰ sur la base du stéroïde non dérivé ».

85. D'après le Dr de Boer, ce document technique imposerait que les valeurs diffèrent de manière significative de trois unités delta ou plus. Par ailleurs, s'agissant d'une valeur seuil, le SIL imposerait l'analyse de trois aliquotes ou, dans l'hypothèse où, comme au cas particulier, un seul aliquote serait disponible, une triple analyse de celui-ci.
86. Le Prof. de Ceaurriz et le Dr Saugy estiment pour leur part qu'une mesure en triplicat de l'échantillon n'est pas nécessaire et qu'une telle exigence, qui n'existerait pas au demeurant, serait au contraire problématique dans la mesure où le volume d'urine nécessaire ne serait pas disponible. Ils indiquent par ailleurs, qu'il ne s'agirait pas d'une mesure à seuil nécessitant l'analyse de plusieurs échantillons.
87. La Formation constate, ici aussi, l'existence d'une divergence d'appréciation entre les experts et considère que Monsieur Landaluce n'a pas renversé la présomption selon laquelle le LNDD s'est conformé au document technique TD2004EAAS.

2. S'agissant des manquements allégués ayant trait à la procédure suivie par le LNDD

a) *L'argument selon lequel les délais n'auraient pas été respectés (points 5.2.4.3.2.1 et 5.2.6.5 du SIL)*

88. Le Dr de Boer fait valoir que le LNDD n'aurait pas respecté les délais prévus par les points 5.2.4.3.2.1 et 5.2.6.5 du SIL.

89. Aux termes du point 5.2.4.3.2.1 du SIL :

« Dans les cas où est demandée une analyse de confirmation sur l'Échantillon "B" de la présence d'une Substance interdite, de Métabolite(s) associé(s) ou de Marqueur(s) indiquant l'Usage d'une Substance interdite ou d'une Méthode interdite, l'analyse de l'Échantillon "B" doit intervenir dès que possible et être conclue dans les trente (30) jours suivant la notification du Résultat d'analyse anormal pour l'Échantillon "A" ».

90. Le point 5.2.6.5 du SIL exige que :

« Les résultats concernant l'Échantillon "A" devront être rendus dans les dix (10) jours ouvrables à compter de la réception de l'Échantillon. [...] Le délai pourra être modifié par accord mutuel entre le Laboratoire et l'Autorité de contrôle ».

91. Le Dr de Boer souligne que les résultats de l'échantillon A, qui auraient dû être rendus dans les 10 jours ouvrables à compter du 14 juin 2005, date de la réception dudit échantillon par le LNDD, ne l'auraient été que 23 jours plus tard, soit le 17 juillet 2005. Le Dr de Boer indique également que l'analyse de l'échantillon B n'aurait pas été réalisée dans le délai imparti de trente jours suivant la notification du résultat d'analyse anormal de l'échantillon A. En effet, la notification du résultat de l'analyse A a eu lieu le 28 juillet 2005. Le LNDD a proposé la date du 11 septembre 2005 pour l'ouverture de l'échantillon B, date qui, à la demande de Monsieur Landaluce, a été reportée au 21 septembre 2005, puis au 19 octobre 2005.

92. L'UCI a reconnu que les délais n'avaient pas été respectés, invoquant « *la surcharge des laboratoires, la complexité de l'analyse et la période des vacances* ».

93. Au cours de l'Audience, l'ensemble des experts présents a déclaré que les délais n'avaient eu aucun effet sur les résultats des analyses.

94. En application des règles relatives aux modes d'établissement des faits et présomptions, la Formation constate que Monsieur Landaluce est parvenu à renverser la présomption selon laquelle le LNDD se serait conformé aux points 5.2.4.3.2.1 et 5.2.6.5 du SIL en démontrant l'existence d'un écart. Une telle démonstration n'a toutefois qu'un effet

purement théorique, l'ensemble des experts présents à l'Audience ayant observé que l'écart constaté ne pouvait être à l'origine du résultat positif de l'analyse des échantillons A et B. La Formation conclut par conséquent que le résultat anormal de Monsieur Landaluce ne résulte pas de l'écart par rapport aux points 5.2.4.3.2.1 et 5.2.6.5 du SIL.

b) *L'argument selon lequel l'analyste qui a effectué l'analyse de l'échantillon B était également impliquée dans l'analyse de l'échantillon A (point 5.2.4.3.2.2 du SIL)*

95. Aux termes du point 5.2.4.3.2.2 du SIL :

« La confirmation sur l'Échantillon "B" doit être réalisée dans le même Laboratoire que celle effectuée sur l'Échantillon "A", par un analyste différent. La (les) opérateurs qui ont effectué l'analyse "A" peuvent toutefois procéder aux réglages instrumentaux, aux contrôles de conformité et à la vérification des résultats ».

96. Monsieur Landaluce se fonde sur le rapport du Dr de Boer pour faire valoir que l'analyste qui a mené l'analyse de l'échantillon B était également impliquée dans l'analyse de l'échantillon A, en violation du point 5.2.4.3.2.2 du SIL.

97. Le Dr de Boer a indiqué que cette norme interdit qu'un même analyste touche/manipule à la fois l'échantillon A et l'échantillon B (*« touching the sample must be separate »*).

98. Au cas particulier, le rapport du 11 juin 2005 révèle que l'analyste qui a procédé à l'analyse de l'échantillon B a, dans le cadre de l'analyse A, réalisé les tâches suivantes : *package* à 4°C, reprise par acétonitrile et mise en vial, évaporation, reprise par hexane et injection CG/MS.

99. Le Président de la Formation a demandé au Dr Saugy si le point 5.2.4.3.2.2 du SIL interdisait que le même analyste touche/manipule à la fois les échantillons A et B. Le Dr Saugy a acquiescé dans les termes suivants : *« je suis d'accord que ça exclut toute manipulation de l'échantillon »*.

100. Le Président de la Formation a ensuite interrogé le Prof. de Ceaurriz afin de savoir si le même analyste avait touché/manipulé les échantillons A et B. Le Prof. de Ceaurriz a répondu :

« Oui. C'est clairement indiqué. Si vous voulez c'est indiqué dans notre chaîne de [sécurité]. Il n'y a pas d'ambiguïté là-dessus. [L'analyste] a touché les échantillons dans le A et a touché la totalité des échantillons dans le B. Il n'y a pas d'ambiguïté là-dessus ».

101. Le Président de la Formation a alors demandé si cela était constitutif d'un écart par rapport au SIL, ce à quoi le Prof. de Ceaurriz a répondu :

« Tout à fait. C'est même ouvertement dans les documents du laboratoire. [...] par rapport à la norme, effectivement, elle a eu un contact avec l'échantillon ».

102. Le Prof. de Ceaurriz a indiqué qu'il y avait eu 10 % de « *chevauchement pour des raisons de charge de travail entre deux personnes* ».

103. L'ensemble des experts présents à l'Audience a donc reconnu que l'analyste qui est intervenue dans le cadre des deux analyses ne s'était pas bornée à « *procéder aux réglages instrumentaux, aux contrôles de conformité et à la vérification des résultats* » et qu'un écart était constaté par rapport au point 5.2.4.3.2.2 du SIL.

104. En application des règles relatives aux modes d'établissement des faits et présomptions, la Formation constate que Monsieur Landaluce parvient une nouvelle fois à renverser la présomption selon laquelle le LNDD se serait conformé au point 5.2.4.3.2.2 du SIL, en démontrant l'existence de cet écart. Les conséquences sont cette fois décisives.

105. Il n'a pas été démontré que cela n'était pas à l'origine du résultat anormal, ni d'ailleurs que cela l'était. Il incombait toutefois à l'UCI, aux termes de l'article 18 du RCAD, de démontrer que l'écart par rapport au SIL n'était pas à l'origine de l'analyse anormale, ce qui n'a pas été fait. L'UCI s'est contentée d'indiquer dans son mémoire d'appel que :

« Et même si écart il y aurait eu – quod non – celui-ci n'a pu conduire au résultat d'analyse anormal, sauf s'il est établi que [l'analyste] avait commis une erreur ayant causé le résultat d'analyse anormal, quod non ».

106. De même lors de l'Audience, l'UCI a simplement observé :

« Quant aux écarts avec le standard qui ont été signalés, je crois pouvoir conclure que s'il y en a eu, ils ne sont pas significatifs et ne sont certainement pas à l'origine du résultat ».

107. Or, il appartenait bien à l'UCI de démontrer que le non-respect du point 5.2.4.3.2.2 du SIL n'était pas à l'origine du résultat anormal. Dans la mesure où l'UCI n'est pas parvenue à ce faire, la Formation ne peut que conclure à la mise hors de cause de Monsieur Landaluce.

108. Il est vrai qu'une sentence ayant eu à se prononcer sur cette question de la double intervention d'un même analyste dans le cadre de l'examen des échantillons A et B, dans l'affaire Wang Lu Na et autres contre FINA (TAS 98/208, sentence du 22 décembre 1998, Wang Lu Na et autres / FINA), a confirmé la suspension de quatre nageuses.

L'apport de cette sentence est toutefois très marginal pour les besoins de la présente affaire, et ce pour trois raisons. Premièrement, la réglementation applicable est différente. Ensuite, la sentence indique expressément (*paragraphe 5.22*) que le rôle joué par les analystes concernés n'était pas clairement établi : les arbitres ont déclaré qu'ils étaient « *unpersuaded* » par l'argument selon lequel les analystes « *were involved in anything other than the tests of the controls* » par opposition aux « *A samples themselves* ». Or, au cas particulier, comme cela a été démontré précédemment, il y a identité des analystes ayant manipulé les échantillons A et B. Enfin, les représentants des nageuses avaient, par leurs signatures, reconnu que la procédure prévue par le règlement de la FINA avait été respectée par le laboratoire. En l'espèce, l'UCI ne s'est pas attachée à rapporter la preuve de ce que Monsieur Landaluce avait approuvé la procédure suivie.

109. Bien que conscient des impératifs de coûts et d'organisation auxquels sont confrontés les laboratoires, la Formation se doit de veiller au respect de règles fondamentales, compte tenu des implications que sa décision pourrait avoir sur la réputation, et partant, la carrière de l'athlète, si une sanction disciplinaire était prononcée à son encontre.
110. La Formation n'est pas sans savoir que la norme qui impose qu'un analyste différent procède à l'analyse de l'échantillon B a fait l'objet de discussions vives entre l'AMA et les responsables de laboratoires. Ces derniers font valoir que cette règle complique déraisonnablement le fonctionnement des laboratoires, sans pour autant qu'il soit démontré qu'elle apporte une protection supplémentaire des athlètes contrôlés. Il serait assurément irréaliste d'exiger qu'un même analyste effectue l'intégralité d'une analyse du début à la fin. En effet, les analyses peuvent, lorsqu'elles portent sur certaines substances, durer plusieurs jours au cours desquels des procédés sont machinalement mis en œuvre. Les analystes effectuent de nombreuses tâches, passant de l'une à l'autre, afin que plusieurs analyses puissent être réalisées simultanément. S'il est envisageable d'exiger d'un grand laboratoire comptant un effectif de 50 à 100 personnes, que le travail y soit organisé de façon à exclure de l'analyse de l'échantillon B l'analyste qui aurait effectué l'analyse de l'échantillon A – bien que cela constitue un facteur de complication non négligeable dont les laboratoires souhaiteraient se dispenser – une telle exigence constituerait un facteur de complication majeur pour un laboratoire de moindre taille.

111. Il est quasiment impossible de prouver un fait négatif, soit en l'occurrence que l'intervention du même analyste dans le cadre des deux analyses n'a pas pu affecter le résultat. Certains responsables de laboratoire estiment par conséquent que cette règle serait trop rigide ; en réalité, une protection suffisante des athlètes est déjà assurée dans la mesure où le système d'identification des échantillons par codes permet de s'assurer de ce que leur identité n'est pas connue des analystes.
112. Ce raisonnement, bien que rationnel et plausible, échoue devant le TAS pour une raison très simple : les arbitres ne créent pas les règles, ils les appliquent. Cela est d'autant plus vrai que les auteurs du règlement antidopage ont conservé la règle qui impose qu'un autre analyste soit chargé de l'analyse de l'échantillon B, alors même qu'ils avaient entendu les observations des responsables de laboratoires. Les règles peuvent certes être modifiées ou affinées, mais tel n'est pas le rôle du TAS.
113. La règle applicable est claire et dépourvue de toute souplesse. Les arbitres du TAS n'ont pas pour mission de modifier les règles ni vocation à s'approprier un pouvoir discrétionnaire lorsque aucun texte ne les autorise à le faire.
114. L'on notera en passant que si les cas où le TAS conclut à la mise hors de cause d'un athlète dans l'hypothèse où un laboratoire n'aurait pas respecté les protocoles sont peu fréquents, cela s'explique par le fait que les autorités disciplinaires connaissent la sévérité des arbitres à cet égard et renoncent à poursuivre les athlètes – même en présence de cas très suspects – lorsque les analyses n'ont pas été réalisées dans le respect des règles de l'art.
115. La Formation tient à souligner la bonne foi du personnel du LNDD qui n'est pas en cause. Les arbitres n'ont aucune raison de douter de l'explication fournie par le Prof. De Ceaurriz selon laquelle le « *chevauchement* » des opérations effectuées par les analystes était dû à une surcharge de travail au sein du LNDD. Il a par ailleurs fait observer que des personnes malveillantes et complices auraient couvert leurs agissements en rédigeant les rapports relatifs aux analyses de façon à ce qu'aucun manquement éventuel ne puisse leur être reproché. Au cas présent, c'est tout le contraire ; l'athlète obtient gain de cause sur la base des informations dont disposait le laboratoire et qui ont été loyalement communiquées.
116. Il convient encore de préciser que les paragraphes 95 à 115 de cette décision ont été adoptés à la majorité de la Formation arbitrale, selon l'article R59 du Code, et que

l'opinion minoritaire de l'arbitre dissident a été dûment considérée et débattue lors des délibérations.

117. En tout état de cause, la présente sentence ne constitue pas une déclaration d'innocence de Monsieur Landaluce au regard des règles antidopage. Monsieur Landaluce bénéficie simplement d'une règle formelle et pourtant fondamentale, tendant à garantir les droits des personnes soumises à des contrôles antidopage.

VI. S'AGISSANT DES FRAIS

118. En ce qui concerne les litiges disciplinaires à caractère international jugés en appel, tel que celui qui nous occupe, l'article R65 du Code prévoit ce qui suit:

« Sous réserve des articles R65.2 et R65.4, la procédure est gratuite.

Les frais et honoraires des arbitres, calculés selon le barème du TAS, ainsi que les frais du TAS sont à la charge du TAS.

Lors du dépôt de la déclaration d'appel, l'appelant verse un droit de Greffe minimum de CHF 500.—, faute de quoi le TAS ne procède pas et l'appel est réputé retiré. Cet émolument reste acquis au TAS.

Les frais des parties, témoins, experts et interprètes sont avancés par les parties. La Formation en attribue la charge dans la sentence en tenant compte du résultat de la procédure, du comportement et des ressources financières des parties.

Si l'ensemble des circonstances le justifie, le Président de la Chambre arbitrale d'appel peut, d'office ou sur demande du Président de la Formation, appliquer les articles R64.4 et R64.5, 1^{ère} phrase, à une procédure arbitrale d'appel ».

119. Les articles R64.4 et R64.5 du Code prévoient ce qui suit :

« A la fin de la procédure, le Greffe arrête le montant définitif des frais de l'arbitrage qui comprennent le droit de Greffe du TAS, les frais administratifs du TAS calculés selon le barème du TAS, les frais et honoraires des arbitres calculés selon le barème du TAS, une participation aux débours du TAS et les frais de témoins, experts et interprètes. Le décompte final des frais de l'arbitrage peut soit figurer dans la sentence, soit être communiqué aux parties séparément ».

« La sentence arbitrale détermine quelle partie supporte les frais de l'arbitrage ou dans quelle proportion les parties en partagent la charge. La sentence condamne en principe la partie qui succombe à une contribution aux frais d'avocat de l'autre partie, ainsi qu'aux frais encourus par cette dernière pour les besoins de la procédure, notamment les frais de témoins et d'interprète. Lors de la condamnation aux frais d'arbitrage et d'avocat, la Formation tient compte du résultat de la procédure, ainsi que du comportement et des ressources des parties ».

120. En l'espèce, l'appel de l'UCI est rejeté et la décision dont appel doit être confirmée. Cet arbitrage étant gratuit pour les parties, dès lors qu'il concerne un litige de nature

disciplinaire à caractère international, il s'agit de déterminer si et dans quelle mesure Monsieur Landaluce et la RFEC ont droit à l'octroi d'une indemnité pour leurs frais d'avocat et pour les autres frais relatifs à la présente procédure d'arbitrage. Après avoir dûment considéré l'ensemble des circonstances de l'affaire, notamment le grand nombre d'arguments futiles invoqués par les défendeurs, la Formation considère qu'il est équitable de laisser à la charge de chacune des parties les frais encourus dans le cadre de cette procédure.

VII. S'AGISSANT DE LA CONFIDENTIALITE

121. Aux termes de l'article R59 alinéa 6 du Code de l'arbitrage en matière de sport :

« La sentence, un résumé et/ou un communiqué de presse faisant état de l'issue de la procédure est publié par le TAS, sauf si les parties conviennent que l'arbitrage doit rester confidentiel ».

122. Monsieur Landaluce a indiqué qu'il souhaitait que la procédure demeure confidentielle et qu'aucun communiqué de presse faisant état de la procédure ne soit publié par le TAS.

123. L'UCI a indiqué que la procédure initiée à l'encontre de Monsieur Landaluce était d'ores et déjà connue du public, celle-ci ayant fait l'objet d'un communiqué de presse par le TAS.

124. Lors de l'Audience, l'UCI, Monsieur Landaluce et la RFEC ne sont pas parvenus à un accord concernant le caractère confidentiel ou non de la présente procédure. Dans ces circonstances, le TAS pourra, s'il le juge opportun, publier un résumé et/ou un communiqué de presse faisant état de l'issue de la présente procédure.

* * * * *

PAR CES MOTIFS

Le Tribunal Arbitral du Sport prononce :

1. Le Tribunal Arbitral du Sport est compétent pour connaître de l'appel interjeté par l'Union Cycliste Internationale.
2. L'appel formé le 26 juin 2006 par l'Union Cycliste Internationale contre la décision rendue le 5 mai 2006 par le Comité Nacional de Competición y Disciplina Deportiva de la Real Federación Española de Ciclismo est rejeté.
3. La sentence est rendue sans frais, à l'exception de l'émolument de greffe de CHF 500 versé en début de procédure par l'Union Cycliste Internationale, qui reste acquis au TAS.
4. Chaque partie garde ses frais d'avocat et autres frais découlant du présent arbitrage.

Lausanne, le 19 décembre 2006

Le TRIBUNAL ARBITRAL DU SPORT

Le Président de la Formation

Jan Paulsson

Olivier Carrard
Arbitre

José Juan Pintó
Arbitre

Shaparak Saleh
Greffier ad hoc

**TAS 2006/A/1119 Union Cycliste Internationale (UCI) v. Iñigo Landaluze Intxaurreaga &
Real Federación Española de Ciclismo (RFEC)**

ARBITRAL AWARD

delivered by the

COURT OF ARBITRATION FOR SPORT

sitting in the following composition:

President: Jan Paulsson, Attorney-at-law, Paris, France

Arbitrators: Olivier Carrard, Attorney-at-law, Geneva, Switzerland
José Juan Pintó, Attorney-at-law, Barcelona, Spain

Ad-hoc Clerk: Shaparak Saleh, Attorney-at-law, Paris, France

in the arbitration between

The Union Cycliste Internationale (UCI), Aigle, Switzerland
Represented by Philippe Verbiest, Attorney-at-law, Leuven, Belgium

versus

Iñigo Landaluze Intxaurreaga, Spain
Represented by Carmen Coello de Portugal Silva and Immaculada Herranz Perlado, Attorneys-
at-law, Madrid, Spain

and

Real Federación Española de Ciclismo (RFEC), Madrid, Spain
Represented by José Antonio del Valle Herán, Attorney-at-law, Madrid, Spain

* * * * *

I. FACTS

1. The Union Cycliste Internationale (**UCI**) is the association of national cycling federations. The purposes of the UCI are to direct, develop, regulate, control and discipline cycling. The antidoping system put in place by the UCI includes the Antidoping Rules (**ADR**), the list of prohibited doping classes of substances and methods, the list of international events subject to doping control and the list of accredited laboratories.
2. The Real Federación Española de Ciclismo (**RFEC**) is the Spanish national cycling federation. It has disciplinary regulations at the national level and is a member of the UCI.
3. Mr. Iñigo Landaluze Intxaurreaga (**Mr. Landaluze**) is a Spanish rider in the elite category, holder of a license granted by the RFEC. At the time of the facts, he was a member of the Euskaltel cycling team and participated in the international road cycling race "Critérium du Dauphiné Libéré" which took place from June 5 to 12, 2005.
4. At the end of the June 11, 2005 stage, Mr. Landaluze underwent a doping control test. During sample collection, Mr. Landaluze indicated that he had taken triamcinolone by infiltration on March 21, 2005.
5. The A sample collected from Mr. Landaluze was analyzed by the French antidoping lab in Châtenay-Malabry (**LNDD**), a laboratory accredited by the World Anti-Doping Agency (**WADA**). Its analytical report dated July 17, 2005 revealed that *"the isotopic ratio mass spectrometric analysis indicates that Testosterone or one of its precursors was taken."* On July 28, 2005, the analytical report for the A sample was communicated to the RFEC, so that disciplinary proceedings would take place, in accordance with article 187 of the ADR.
6. On August 11, 2005, Mr. Landaluze requested, via the RFEC, a B sample analysis. He then asked that the B sample analysis, which was originally scheduled for September 14 and 21, 2005, be postponed to October 19, 2005. On October 21, 2005, the B sample analysis confirmed the presence of exogenous testosterone in the B sample.
7. By a fax dated October 27, 2005, the UCI communicated the B sample analysis results to the RFEC and asked the latter to proceed with the disciplinary proceedings.
8. On May 5, 2006, the RFEC, via the Comité Nacional de Competición y Disciplina Deportiva (national committee for competition and sport discipline/**CNCDD**) deemed that the conditions in which the analysis had been done revealed the existence *"of an incomplete process not in conformity with all applicable legal requirements which, therefore, could not totally guarantee the result."* The CNCDD determined that *"the legal principle, 'in dubio pro reo' [giving the defendant the benefit of the doubt], [was] fully applicable to the present case,"* shelved the case and acquitted Mr. Landaluze.
9. Mr. Landaluze did not participate in any cycling race between July 24, 2005 and May 15, 2006.

II. PROCEEDINGS

A. PARTIES' SUBMISSIONS

10. The UCI brought the case before the Court of Arbitration for Sport (**CAS**) in a statement dated June 26, 2006.

On July 17, 2006, the UCI filed its appeal brief requesting that the CAS:

- "1) overturn the decision of the RFEC national committee for competition and sport discipline;*
- 2) suspend Mr. Landaluce Intxaurreaga for 2 years, in accordance with the ADR;*
- 3) disqualify Mr. Landaluce Intxaurreaga from cycling races in which he participated beginning June 11, 2005, including in particular the cycling race "Critérium du Dauphiné Libéré", until at least July 29, 2005.*
- 4) order Mr. Landaluce Intxaurreaga and the Real Federación Española de Ciclismo to pay the UCI the sum of 1,000 Swiss francs for the costs of managing the results (ADR article 245.2).*
- 5) order Mr. Landaluce Intxaurreaga and the Real Federación Española de Ciclismo to reimburse the UCI for the fee of 500 Swiss francs and all other costs, including a contribution to the UCI costs."*

11. Mr. Landaluce filed his response on September 8, 2006, requesting that the CAS:

- declare that it has no jurisdiction on this case;
- order the UCI to pay the costs generated by the proceedings.

Mr. Landaluce made the subsidiary request that the CAS:

- dismiss the appeal filed by the UCI;
- order no sanction against him;
- order the UCI to pay costs.

Mr. Landaluce made the even more subsidiary claim that any sanction against him would have to be reduced by nine and a half months, the period during which he abstained from racing.

12. The RFEC filed its response on September 14, 2006, essentially claiming that:

- the CNCDD decision must be confirmed;
- the UCI appeal must be dismissed;

- the UCI must be ordered to pay costs, in accordance with article 282 of the ADR.

B. THE HEARING

13. The hearing took place on October 11, 2006, at the CAS Head office in Lausanne (The *Hearing*), in the presence of the three members of the Court of Arbitration (the *Panel*) and of the attorneys for the parties.

14. The Panel heard the following witnesses and experts:

- For the UCI:

- Doctor Martial Saugy, director of the Swiss antidoping laboratory (*Dr. Saugy*);
- Professor Jacques de Cœuriz, LNDD director (*Prof. De Cœuriz*).

- For Mr. Landaluce:

- Dr. Douwe de Boer, a researcher at the Clinical Chemistry Laboratory at the Maastricht University Hospital and former director of the Doping Department of the Lisbon Analytical and Doping Laboratory (*Dr. de Boer*);
- Dr. Detlef Thieme, a forensic toxicologist expert at the forensic toxicology department of the Munich Forensic Medicine Institute (*Dr. Thieme*);
- Mr. Ignacio Colomer Hernández, a Law Professor at the Carlos III University in Madrid (*Prof. Colomer*), by videoconference.

C. ON MR. LANDALUCE ENTERING EXHIBITS 43 AND 43 BIS AND ON HEARING MR. MIGUEL MADARIAGA

15. On September 22, 2006, 14 days after filing his response, Mr. Landaluce submitted supplementary exhibits 43 and 43bis.

16. Since the UCI was opposed to said exhibits 43 and 43bis being entered, Mr. Landaluce indicated, by fax dated 2 October 2006, that he wanted Mr. Miguel Madariaga (*Mr. Madariaga*) to testify as a witness.

17. By fax dated 4 October 2006, the UCI opposed the testimony of Mr. Madariaga, since Mr. Landaluce's response did not mention this witness's testimony at all.

18. According to article R56 of the Code of Sports-related Arbitration:

"Unless the parties agree otherwise or the President of the Panel orders otherwise on the basis of exceptional circumstances, the parties shall not be authorized to supplement their argument,

nor to produce new exhibits, nor to specify further evidence on which they intend to rely after the submission of the grounds for the appeal and of the answer."

19. During the hearing, the UCI indicated that it would agree to let Mr. Madariaga testify only if it could add to the debate a new piece of evidence received the day before. The Panel President asked that the evidence be forwarded to the RFEC and to Mr. Landaluce, to make them aware of it. Upon seeing the evidence, Mr. Landaluce dropped his request for Mr. Madariaga to testify.
20. In the absence of "*exceptional circumstances*" in the sense of article R56 of the Code of Sports-related Arbitration, the Panel President decided not to admit the new evidence and not to hear the witness.

III. ON THE COMPETENCE OF THE CAS

21. The organization of professional competitions assumes a clear distribution of competence between national and international authorities, on the one hand, and between the public and private sector, on the other hand.
22. There are domains, such as narcotics trafficking, in which the state requires, in the name of national sovereignty, control over any reprehensible behavior within the country, and refuses to let private associations take charge, including via a delegation of public service.
23. In contrast, discipline in the sports domain, which results in disqualifying the athlete or prohibiting the athlete from participating in future competitions, essentially reflects the will to eliminate unfair competition. This is why it is legitimately entrusted to sports authorities.
24. This is even truer when it comes to the exercise of sport at the international level, which cannot obey a multiplicity of potentially contradictory national rules.
25. To trust national laws alone with the management of international competitions would lead to an incoherent and non-egalitarian system, with the added risk that national authorities would sooner or later try to legislate as leniently as possible.
26. To alleviate such inconveniences, it suffices to ensure that the same sport discipline, when it takes place in an international context, is subject to the same rules for all competitors.
27. Mr. Landaluce tried to cause the Panel to believe that the legal situation in Spain would dictate a different solution. He claimed that the CAS is not competent to hear the UCI appeal against a CNCDD decision and indicates that only the Spanish Committee for Sports Discipline of the Superior Council of Spanish Sports (*SCSD*) is competent.
28. To support his claim, Mr. Landaluce invoked a certain number of texts which are reproduced below:

- Article 6 of the UCI Constitution:

- "1. As members, the federations shall comply with the Constitution and Regulations of the UCI, as well as with all decisions taken in accordance therewith. Likewise, they shall have the Constitution, Regulations and decisions of the UCI complied with by all persons concerned.*
- 2. The Regulations of the UCI shall be incorporated in the corresponding regulations of the federations.*
- 3. The constitution and regulations of the federations shall not run counter to the Constitution and Regulations of the UCI. In case of divergence, only the Constitution and Regulations of the UCI shall apply. The constitution and the regulations of the federations must contain an express clause that in case of divergence with the Constitution and Regulations of the UCI, only the latter shall apply.*
- 4. The foregoing paragraphs shall be applied in observance of the mandatory legal provisions in force in the country of the federation concerned."*

- Article 35 of the Royal Decree 1835/1991 of 20 December 1991 relative to Spanish sports federations:

"The following questions cannot be subject to conciliation or arbitration: [...]

b) Those relative to the control of substances and methods prohibited in sport and the safety of the practice of sport ...]."

- Article 90.2 of the RFEC Constitution in its version following the decision of 11 October 2004:

"The following questions cannot be subject to conciliation: [...]

b) Those relative to the control of substances and methods prohibited in sport and the safety of the practice of sport ...]."

- Section 24 of the Spanish Constitution of 28 December 1978:

"1. All persons have the right to obtain effective protection from the judges and the courts in the exercise of their rights and legitimate interests, and in no case may there be a lack of defense.

2. Likewise, all have the right to the ordinary judge predetermined by law; to defense and assistance by a lawyer; to be informed of the charges brought against them; to a public trial without undue delays and with full guarantees; to the use of evidence appropriate to their defense; not to make self-incriminating statements; not to plead themselves guilty; and to be presumed innocent."

- Article 91.1 of the RFEC Constitution in its version following the decision of 11 October 2004:

"A commitment to undergo the conciliation proceedings will be required from the parties in the litigation. To this end, a written arbitration agreement must include an agreement that the arbitration award shall be final, and the obligation to accept the decision of one or more arbitrators, and the procedural rules."

- Article 84.1 of the Law 10/1990 of 15 October 1990 relative to Sport:

"The Spanish Committee for Sport Discipline is the national organ organically appointed to the Superior Council for Sports which, acting independently from the latter, resolves in final appeal, by administrative procedure, disputes on sports disciplinary questions that fall under its jurisdiction."

- Article 10 of the RFEC Constitution:

"1. Under the coordination and guardianship of the Superior Council for Sports, the RFEC will exercise the following public functions of administrative nature: [...]"

f) Exercise sports disciplinary authority, according to the terms established by the Law on Sport, its particular provisions for development and its statutes and regulations."

- Article 59 of the Royal Decree 1591/1992 of 23 December 1993:

"The competence of the Spanish Committee for Sports Discipline extends to the following:

a. taking notice of and making decisions on appeals concerning the acts of sports entities with disciplinary authority when the remedies offered by sport procedures have been exhausted, according to the distribution of competence established by the Law on Sport and by the present royal decree."

29. Essentially, Mr. Landaluce claimed:

- that arbitration in matters of doping is prohibited in Spain;
- that the Spanish Constitution contains an inalienable right of access to justice and the courts. Mr. Landaluce indicated that he cannot be deprived of this constitutional right of access to justice by being authorized to appeal only before the CAS;
- that he never agreed to CAS arbitration and never signed any arbitration agreement. Mr. Landaluce considers that the mere fact that he holds a RFEC license can in no way constitute acceptance of the competence of the CAS;
- that the RFEC is a public authority exercising public disciplinary functions under the guardianship of a Spanish public entity. Therefore, Mr. Landaluce considers that the RFEC decisions should be subject to an administrative appeal before the CEDS, followed, as needed, by an appeal before the Spanish administrative judge;
- that according to article 6, item 4 of the UCI Constitution, the RFEC must respect Spanish legislation when it applies the UCI standards;

- that articles 242 and 280 of the ADR, which establish the exclusive competence of the CAS to take notice of the appeal against the decisions of national federations, are not applicable, according to article 6.4 of the UCI Constitution, since this exclusive competence would violate Spanish law;

- that the Central Administrative Litigation Court Number 7 of Madrid judgment of 8 June 2006 rendered in a Santiago Perez Fernandez case recognizes the possibility of appeal against the decisions of the CNCDD in a hierarchical sequence: before the SCSD followed, as needed, by an appeal before the Spanish administrative judge.

30. The UCI considers the CAS competent and the ADR applicable, on the basis of the following texts:

- Article 1.1.001 of the UCI Rules:

"The licence is an identity document confirming that its holder undertakes to respect the constitution and regulations and which authorise [sic] him to participate in cycling events."

- Article 1.1.004 of the UCI Rules:

"Anyone requesting a licence thereby undertakes to respect the constitution and regulations of the UCI, the UCI continental confederations and the UCI member Federations, as well as to participate in cycling events in a sporting and fair manner. He shall undertake, in particular, to respect the obligations referred to in article 1.1.023."

As from the time of application for a licence and provided that the licence is issued, the applicant is responsible for any breach of the regulations that he commits and is subject to the jurisdiction of the disciplinary bodies.

Licence holders remain subject to the jurisdiction of the relevant disciplinary bodies for acts committed while applying for or while holding a licence, even if proceedings are started or continue after they cease to hold a licence."

- Article 1.1.023 of the UCI Rules:

*"[...] 2. I hereby undertake to respect the constitution and regulations of the International Cycling Union, its continental confederations and its national federations.
I declare that I have read or have had the opportunity to become acquainted with the aforesaid constitution and regulations.
I shall participate in cycling competitions or events in a sporting and fair manner.
I shall submit to disciplinary measures taken against me and shall take any appeals and litigation before the authorities provided for in the regulations. I accept the Court of Arbitration for Sport (CAS) as the sole competent body for appeals in such cases and under the conditions set out in the regulations."*

I accept that the CAS shall be the court of last instance and that its decisions shall be definitive and without right of appeal. With those reservations, I shall submit any litigation with the UCI solely to the courts within whose jurisdiction the head offices of the UCI lie.

3. I agree to submit to and be bound by the UCI antidoping regulations, the clauses of the World Antidoping Code and its international Standards to which the UCI antidoping regulations refer and to the antidoping regulations of other competent bodies as per the regulations of the UCI and the World Antidoping Code provided that they comply with that Code.[...]"

- Article 5 of the UCI Rules Preliminary provisions:

"Participation in a cycling race, in whatever capacity, shall imply acceptance of all provisions of the Regulations applying thereto."

31. The UCI indicated that the review of the above articles together essentially means that:

- riders who hold licenses from UCI member federations are subject to the ADR;
- any person who applies for a license undertakes to respect the ADR and especially to be subjected to doping control tests and to the competence of the CAS as the court of last instance.

32. To support its claim, the UCI cited the fact that the decision of the CNCDD dated 5 May 2006, which is being appealed, was rendered by applying the ADR.

33. In addition, during the hearing, the UCI claimed that:

- the CAS should assess competence and arbitrability in disputes according to the Swiss federal law on private international legislation (**LDIP**) under whose terms (i) doping can be subject to arbitration, and (ii) arbitration clauses by reference are valid (article 178 of the LDIP);
- according to the CAS jurisprudence, the existence of a national law does not preclude the application of the regulations of the international federation (TAS 2005/A/872, arbitral award dated 30 January 2006, UCI /Federico Muñoz Fernandez and Federación Colombiana de Ciclismo);
- the Spanish legislation invoked by Mr. Landaluce would be intended to apply only in Spain, as shown in the following:
 - (i) article 1.3° of Royal Decree 1835/1991 dated 20 December 1991 on Spanish sports federations, according to which the scope of competence of Spanish sports federations would be limited to within the country;
 - (ii) the preamble of Law 10/1990 dated 5 October 1990 on sport, according to which the object of the law would be to define the legal framework applicable to the practice of sport within Spain.
- article 7 of the Royal Decree 255/1996 dated 16 February 1996, according to which the sanctions imposed in application of the antidoping rules of any federation, be it national,

international or autonomous, have effects in all of Spain, shows that sanctions can be imposed by federations other than RFEC and have effects within Spain;

- to admit, as the sole appeal procedure against CNCDD decisions, an appeal before the SCSD would be equivalent to depriving the UCI of any right of oversight on the decisions arising from the national federation, to the extent that the UCI would not be able to appeal within Spanish jurisdiction.

34. In its writings and during the hearing, the RFEC indicated that it was won over to the UCI's interpretation, with regard to the competence of the CAS. In addition, the RFEC indicated that it was a private entity "*wearing two hats*" exercising, on a case by case basis, missions of a public or private nature. The RFEC stated that in the context of international competitions, such as the case in point, it exercises a mission of a private nature.

35. During the hearing, Prof. Colomer claimed the following:

- the granting of a license by the RFEC constitutes an administrative act;
- the power of sanction of the RFEC is applied in the context of the exercise of a public function;
- the CAS is not competent because the sanction imposed by the CNCDD is an administrative act;
- the fact that arbitration is prohibited in matters of doping is imperative for the parties, with no possible exception;
- the Spanish Constitution prevails over any international treaty;
- any decree contrary to the Spanish Constitution is unconstitutional;
- article 7 of Royal Decree 255/1996 dated 16 February 1006 is unconstitutional.

36. The Panel, aware of the fact that the present dispute illustrates the tension that can exist between an athlete's national law and the regulations of the international federation to which he is subjected, recalls that the UCI is the association of national cycling federations, and that the purposes of the UCI are to direct, develop, regulate, control and discipline international cycling, particularly in matters of doping. As for Mr. Landaluce, he is a professional cyclist in the elite category, holder of a license under the terms of which he accepted to be subject to the UCI regulations.

37. Mr. Landaluce's application for a license certainly shows that the model used by the RFEC to apply for a license does not conform to the UCI Rules. However, articles 2 and 3 of the application for a license signed by Mr. Landaluce indicates that its holder commits himself to respect the current Spanish legislation, the Constitution of the UCI and of its confederations as well, and that he agrees to be subject to doping control tests in the conditions set out in article 1.1.023 of the UCI Rules as well as to the competence of the CAS which is explicitly

set out. The RFEC did indicate, during the Hearing, that the fact of applying for a RFEC license is in itself equivalent to accepting the competence of the CAS, even in the absence of an explicit clause to this effect. The Panel considers that by requesting a license from the RFEC, Mr. Landaluce subjected himself to the competence of the CAS, as well as to the UCI Rules.

38. Some might think that it would have been preferable for the application for a license to mention specifically that the parties agreed to CAS arbitration. In this regard, the Panel emphasizes that elite riders are not lay persons, such as consumers might be, but informed athletes undoubtedly aware of the existence of the CAS and of its competence in matters of doping. Therefore, the competence of the CAS as set out in article 1.1.023 of the Cycling Sport Rules can in no way be a surprise to a person who applies for a license. To require that, in addition to the elements listed in paragraph 37, a license application must mention explicitly the competence of the CAS in order for the CAS to be competent, would be an excessive formality and a demand not required by the jurisprudence of the Swiss federal court.
39. Mr. Landaluce's argument that article 6 paragraph 4 of the UCI Constitution orders the RFEC to apply Spanish law and forbid CAS arbitration doesn't do much to convince the Panel. In fact, article 6 of the UCI Constitution is aimed only at national federations. The first three paragraphs of this article require these federations to harmonize their rules by reiterating the UCI rules. The fourth paragraph of article 6 of the UCI Constitution simply indicates that this harmonization must take into account potential requirements applicable in the federation's country. Consequently, article 6 paragraph 4 of the UCI Constitution explicitly refers to the three preceding paragraphs and cannot be taken out of context. Thus Article 6 of the UCI Constitution addresses only national federations, to indicate to them the procedure to follow to harmonize their rules, and cannot be invoked by a cyclist in order to escape the application of the UCI Rules, and by doing so, the competence of the CAS.
40. After all, no provision of Spanish law excludes arbitration. This is certainly not the case with article 24 of the Spanish Constitution. To be convinced, it suffices to compare the scope of this text to that of article 6 paragraph 1 of the European Convention on Human Rights (*ECHR*) which states that "*everyone is entitled to a fair and public hearing [...] by an independent and impartial tribunal established by law.*" The European Convention on Human Rights decided in the case of X./RFA dated 5 March 1962, that the insertion of a compromissory clause in a contract was equivalent to renouncing the benefit of the ECHR and that no stipulation of the ECHR forbade such a renunciation. Unless otherwise demonstrated, article 24 of the Spanish Constitution, exactly like article 6 paragraph 1 of the ECHR, in no way forbids arbitration. In fact, the competence of the CAS does not deprive Mr. Landaluce of his right to have access to justice as set out by the Spanish Constitution, since arbitration is a form of exercise of this right in an international matter.
41. Finally, the Panel considers that the Spanish provisions invoked by Mr. Landaluce are intended to apply only in the context of national cycling competitions, and cannot be an obstacle to applying the UCI Rules or the competence of the CAS. To decide otherwise would lead to a veritable race for the most lenient national legislation.

42. Indeed, international sports federations such as the UCI must have a right to oversee the decisions of national federations in matters of doping. This right of oversight of the UCI's, which manifests itself by the ability to appeal the decisions of national federations before the CAS, is there to reduce the risk that an international competition would be biased by a national federation that would refrain from sanctioning its members.
43. Therefore, Mr. Landaluce's argument that the sole recourse against the decisions of the CNCDD would be an appeal before the SCSD cannot win the support of the Panel.
44. Likewise, Mr. Landaluce's argument contesting the competence of the CAS because anti-doping rules would be trusted to a public authority is flawed. In fact, a review of CAS jurisprudence indicates that the power of international federations such as the UCI is exercised even when doping control and sanctions are trusted, as in the case in point, to a public authority.
45. The power of international federations is there to eliminate unfair competition and any hunt for the most lenient legislation. It tends to subject all athletes to equal treatment, by seeing to it that certain national federations won't remain passive in view of offenses committed by their country's athletes. Thus, in a doping case involving swimmers in 1997, the CAS recognized as an imperative necessity for international federations to be able to review the decisions of national federations in doping cases. This is to prevent the risk that international competitions would be biased, because a national federation might be tempted to pronounce sanctions that would be too lenient (TAS 96/156, arbitral award dated 10 October 1997, F. / FINA).
46. Later on, another CAS panel had the opportunity to extend this jurisprudence to sanctions pronounced by national public authorities, in B. v. International Judo Federation on 17 March 1999 (TAS 98/214, arbitral award dated 17 March 1999, B./Fédération Internationale de Judo). This was the case of a positive doping control test sanctioned by a suspension imposed by an order of the French Minister of Sports. Indeed, a 1989 French law gave said minister the power to substitute his decision to any punitive measure taken by national sports federations. In the case in point, the French Federation had imposed a two-year suspension, of which one year was stayed, and the ministry's order substituted a simple one-year suspension. However, the latter sanction was not in conformity with the rules of the International Judo Federation (*IJF*), which brought the case before the CAS. The latter ordered a 15-month suspension.
47. In that arbitral award, the arbitrators evoked the problem that is at the heart of the present dispute:
- "The panel's opinion is that the latitude granted by this jurisprudence to international federations must be extended to the cases in which the doping control procedure and doping sanction are not handled by a national federation, according to sport rules, but by a public authority applying a national law, as in the case in point, or, in relevant cases, based on an international convention."*

The power to extend, at the international level, national decisions relative to doping, no matter what authority rendered them, is justified not only to prevent the risk that certain federations or government entities would engage in unfair competition of the unhealthiest sort, by failing to sanction their athletes as rigorously and severely as other federations and/or their international federations, but also to reach the goal that each international federation must try to achieve, which is to make all participants of the same sport respect an equal and consistent treatment."

48. Therefore, the provisions of the Spanish law that are referred to do not allow to conclude to the lack of competence of the CAS. This is what the CAS determined on several occasions, particularly in cycling in the Muñoz case (TAS 2005/A/872, arbitral award dated 30 January 2006, UCI /Federico Muñoz Fernandez and Federación Colombiana de Ciclismo):

"The panel is prepared to accept that as a matter of Colombian Law it was possible for Mr. Muñoz to appeal to the General Disciplinary Committee of the Colombian National Olympic Committee. However, to do so was a breach of his contract with the UCI. At best, the decision of the General Disciplinary Committee could only have an effect within Colombia. It would not entitle Mr. Muñoz to participate in cycle races organized under the auspices of the UCI, or to avoid the UCI's disciplinary code." [in English in the original document]

49. The authority of States and that of international sport are not in competition; on the contrary, their roles are complementary. The state authority is limited to controlling the behavior of persons subject to its jurisdiction, whereas the international federation manages the competitions that fall under its jurisdiction. One and the same behavior can lead to a penal sanction in a given place, without leading to the cyclist being sanctioned at the international level. Likewise, a behavior can lead to no penal sanctions while it can generate an exclusion from sports contests because it damages the fairness of competition.

50. This complementarity between state and international sport authorities can take on a particular form when a public authority substitutes itself to the national federation to decide on sanctions—as was the case in the above IJF case, or in the case in point. National sovereignty, as expressed when a sport disciplinary measure is taken by a national authority, applies in principle only within the country. However, the national decision can be replaced by a decision of the international authority—the CAS—in order to ensure the necessary legal uniformity. It is certainly theoretically conceivable that the State would impose its national decisions in international competitions taking place within the country, disregarding the international authority. Such a behavior, however, would go against all the efforts made in the fight against doping at the international level, and could lead to excluding that State from organizing international competitions. It would be surprising for a State to want to put itself in such a position, and there is nothing in the texts invoked in the present case that would suggest that Spain would have adopted this position. Quite the contrary, the preamble of the Royal Decree 255/1996 dated 16 February 1996 clearly reflects the fact that Spain is concerned with whether its standards conform to international standards:

"In accordance with article 76.1.d) of the Law on Sport and in accordance with the criteria of international sports standards, the present Royal Decree identifies the behaviors that constitute doping infractions and establishes the relevant sanctions [...]."

51. Far from supporting Mr. Landaluce's claim, the Royal Decree 255/1996 dated 16 February 1996 that he invokes only confirms the reasoning developed above. Indeed, article 7 of this Decree explicitly recognizes that the sanctions imposed by an international federation have effects on all of Spain. The contrary would have been surprising, to say the least.
52. In view of the above, the Panel concludes that it is competent in the present litigation, in accordance with articles 280 to 291 of the ADR.
53. This is in fact not contested by the RFEC which has, during the entire proceedings, recognized the competence of the CAS and the applicability of the ADR, which were explicitly referred to in the CNCDD decision of 5 May 2006, which is the subject of the present appeal.

IV. ADMISSIBILITY

54. Article 285 of the ADR states that the UCI appeal brief must be filed with the CAS within a month after receiving the complete dossier of the national federation hearing. However, when the UCI has not requested the dossier within 15 days after receipt of the decision, as per article 247 of the ADR, the deadline for appeal is one month from receipt of the complete decision.
55. In the case in point, the UCI received the CNCDD decision on 9 May 2006 and requested the complete dossier on 11 May 2006. The complete dossier was received by the UCI on 26 May 2006. The appeal brief was sent on 26 June 2006, by the deadline.

V. MERITS

A. GENERAL PRINCIPLES

56. According to article 16 of the ADR:

"The UCI and its National Federations shall have the burden of establishing that an anti-doping rule violation has occurred. The standard of proof shall be whether the UCI or its National Federation has established an anti-doping rule violation to the comfortable satisfaction of the hearing body bearing in mind the seriousness of the allegation which is made. This standard of proof in all cases is greater than a mere balance of probability but less than proof beyond a reasonable doubt. Where these Anti-Doping Rules place the burden of proof upon the Rider or other Person alleged to have committed an anti-doping rule violation to rebut a presumption or establish specified facts or circumstances, the standard of proof shall be by a balance of probability."

57. On the methods of establishing facts and presumptions, article 18 of the ADR sets out the following:

"WADA-accredited laboratories or as otherwise approved by WADA are presumed to have conducted Sample analysis and custodial procedures in accordance with the International Standards for laboratory analysis. The Rider may rebut this presumption by establishing that a departure from the International Standard occurred.

If the Rider rebuts the preceding presumption by showing that a departure from the International Standard occurred, then the UCI or the National Federation shall have the burden to establish that such departure did not cause the Adverse Analytical Finding."

In other words, there is a refragable presumption that WADA-accredited laboratories conduct analyses in accordance with prevailing and acceptable standards of scientific practice, in accordance with the International Standard for Laboratories (ISL). In the event that the rider demonstrates a departure from the ISL, it is then the UCI's burden to demonstrate that this departure is not at the origin of the adverse analytical finding. Therefore these rules must be applied to determine whether Mr. Landaluce has established that there were departures, and if so, whether the UCI can demonstrate that the departure cannot have caused the adverse finding.

58. According to article 15.1 of the ADR:

"The following constitute anti-doping rule violations:

1. The presence of a Prohibited Substance or its Metabolites or Markers in a Rider's bodily Specimen.

1.1 It is each Rider's personal duty to ensure that no Prohibited Substance enters his body. Riders are responsible for any Prohibited Substance or its Metabolites or Markers found to be present in their bodily Specimens. Accordingly, it is not necessary that intent, fault, negligence or knowing Use on the Rider's part be demonstrated in order to establish an anti-doping violation under article 15.1."

59. The substance testosterone is an endogenous androgenic anabolic steroid, a prohibited substance listed in the 2005 Prohibited List in class S1.1.b. The prohibited lists states the following:

"Where a Prohibited Substance (as listed above) is capable of being produced by the body naturally, a Sample will be deemed to contain such Prohibited Substance where the concentration of the Prohibited Substance or its metabolites or markers and/or any other relevant ratio(s) in the Athlete's Sample so deviates from the range of values normally found in humans that it is unlikely to be consistent with normal endogenous production. A Sample shall not be deemed to contain a Prohibited Substance in any such case where the Athlete proves by evidence that the concentration of the Prohibited Substance or its metabolites or markers and/or any other relevant ratio(s) in the Athlete's Sample is attributable to a physiological or pathological condition. In all cases, and at any concentration, the laboratory will report an Adverse Analytical Finding if, based on any reliable analytical method, it can show that the Prohibited Substance is of exogenous origin.

If the laboratory result is not conclusive and no concentration as referred to in the above paragraph is found, the relevant Anti-Doping Organization shall conduct a further investigation if there are serious indications, such as a comparison to reference steroid profiles, for a possible Use of a Prohibited Substance.

If the laboratory has reported the presence of a T/E ratio greater than four (4) to one (1) in the urine, further investigation is obligatory in order to determine whether the ratio is due to a physiological or pathological condition, except if the laboratory reports an Adverse Analytical Finding based on any reliable analytical method, showing that the Prohibited Substance is of exogenous origin."

B. APPLICATION OF THE GENERAL PRINCIPLES TO THE PARTICULAR CASE

60. In this particular case, the LNDD used, as an analysis method, GC/C/IRMS, analysis by isotopic ratio mass spectrometry. The LNDD analytical report states the presence of exogenous testosterone. The A sample had a T/E ratio of 9.2, greater than the limit of 4 established by WADA. The LNDD B sample analytical report confirmed the A sample analysis result.
61. Since the LNDD conducted analyses whose results are positive, it is Mr. Landaluce's burden to demonstrate that there was a departure from the ISL in order to reverse the presumption that the analyses were conducted in accordance with prevailing and acceptable standards of scientific practice. As justifiably recalled by UCI during the hearing, Mr. Landaluce may not simply indicate that *"something could potentially be wrong"* [quote in English in the original document], but must indeed prove that there was a violation of the ISL.
62. To do so, Mr. Landaluce contested the validity of the LNDD analyses, invoking failures and irregularities during the process. He claimed that there irregularities *"invalidate"* the analysis results and indicated that *"these results will never be considered to prove that a fault was committed that can be sanctioned."*
63. To this end, Mr. Landaluce emphasized that he relied on the observations of Dr. de Boer and of Mrs. Luisa Lurueña Sánchez, a pharmacist and expert in the analysis and quality control of medicines and drugs.
64. Mrs. Luisa Lurueña Sánchez noted the following:
- "The documentation provided is insufficient to demonstrate the abuse of testosterone or a precursor.*
Given the bad, weak and inconsistent analytical documentation shown to demonstrate the abuse of testosterone or analogs in this sample, the athlete's innocence can be defended."
65. In support of his claims, Mr. Landaluce also provided numerous reports by Dr. de Boer who claimed that several irregularities were committed by the LNDD and emphasized that the ISL was not met. In his report dated 12 March 2006, Dr. de Boer stated the following in particular:

"The WADA laboratory in Châtenay-Malabry made no mistake with regard to the chemical analysis, but it did not meet, in several ways, the WADA international standards for analytical Laboratories (ISL, International Standards for Laboratories). Therefore, several nonconformities occurred, which, among other things, resulted in the "A" and "B" sample analysis being far from complete."

66. Mr. Landaluce invoked six departures from the ISL allegedly committed by the laboratory. Four of the alleged departures have to do with scientific interpretation by the laboratory, whereas the other two have to do with the proceedings initiated by him. The Panel must examine the alleged irregularities invoked by Mr. Landaluce to determine whether the LNDD met the ISL.

1. Alleged failures concerning scientific interpretation by the LNDD

a) The argument that the documentation does not allow another analyst to evaluate the analyses and interpret data (point 5.2.6.1 of the ISL)

67. According to point 5.2.6.1 of the ISL:

"The Laboratory must have documented procedures to ensure that it maintains a coordinated record related to each Sample analyzed. In the case of an Adverse Analytical Finding, the record must include the data necessary to support the conclusions reported (as set forth in the Technical Document, Laboratory Documentation Packages) In general, the record should be such that in the absence of the analyst, another competent analyst could evaluate what tests had been performed and interpret the data."

68. Dr. de Boer declared that he could not evaluate different aspects of the analyses because of a lack of information and indicated that the A and B sample reports did not contain information allowing the identification of the steroids in question.

69. As for Dr. Saugy, he indicated that the information allowed the identification of the steroids in question. Indeed, in his declaration dated 14 July 2006, Dr. Saugy indicated that *"after careful and reasonable review of the documentation packages, I have determined that all the elements allowing an evaluation of the dossier are included in it."*

70. The Panel notes that there is a disagreement between the experts. Whereas Dr. Saugy found that the documentation made it possible to identify the steroids in question, Dr. de Boer considered that the elements at his disposal were insufficient. The arbitrators consider that Dr. Saugy's testimony is plausible and that Dr. de Boer's demonstration does not invalidate Dr. Saugy's analysis.

71. Therefore, the Panel's opinion is that Mr. Landaluce has not demonstrated a violation of point 5.2.6.1 of the ISL and that he has not succeeded in reversing the presumption according to which the LNDD analysis was done in accordance with prevailing and acceptable standards of scientific practice, as per point 5.2.6.1 of the ISL.

b) the argument that the substance found is a threshold substance and that the uncertainty of 0.8 adopted by the LNDD would be insufficient (point 5.4.4.1.3 of the ISL)

72. According to point 5.4.4.1.3 of the ISL:

"For both Non-threshold and Threshold Substances, the Laboratory will be required to meet a Minimum Required Performance Limit for detection, identification, and demonstration that a substance exceeds the threshold (if required)."

73. Dr. de Boer's opinion was that the uncertainty value of 0.8 presented by the LNDD was insufficient and should be 1.35. In addition, he indicated that the fact that an uncertainty index was given shows that the LNDD considered the substance to be a threshold substance to the extent that uncertainty is taken into account only for threshold substances. Dr. de Boer concluded that there was a departure from point 5.4.4.1.3 of the ISL.

74. As for Prof. de Ceaurriz and Dr. Saugy, their opinion was that this value, used by many laboratories, is in compliance with point 5.4.4.1.3. of the ISL. In his declaration dated 14 July 2006, Dr. Saugy did not consider it to be a measurement of a threshold substance, but a confirmation method based on quantitative measurements, whose goal is to demonstrate the qualitative origin of the product ingested.

75. The UCI argued that it is not a threshold substance to the extent that the mere presence of exogenous testosterone suffices. The isotopic analysis aims solely to demonstrate the exogenous nature of the product, without any concern for its quantity.

76. To support its allegation, the UCI referred to point 5.4.4.3 of the ISL which indicates the following:

"In most cases an identification of a Prohibited Substance, its Metabolite(s) or Marker(s), is sufficient to report an Adverse Analytical Finding. Thus, quantitative uncertainty as defined in ISO/IEC 17025 does not apply. In the identification of a compound by GC/MS or HPLC/MS, there are qualitative measures that substantially decrease the uncertainty of identification.

In the case of a Threshold Substance, uncertainty in both the identification and the finding that the substance is present in an amount greater than the threshold concentration must be addressed."

77. In his declaration dated 14 July 2006, Dr. Saugy noted that the WADA Technical Document TD2004EAAS indicates that the result demonstrates the administration of an exogenous steroid when the metabolite value differs significantly by 3% or more from that of the endogenous reference chosen. Dr. Saugy declared that in the case in point, the analysis revealed, for both the A and B samples, a difference significantly greater than 3%, namely 4.85% for the A sample and 4.76% for the B sample, between the endogenous reference and the metabolite found in the testosterone.

78. The Panel notes that there is no precise method in this matter and that the experts present at the Hearing did not reach agreement on an uncertainty value to take into account for isotopic analysis.

79. The Panel's opinion is that Mr. Landaluce has not reversed the presumption that the LNDD conducted its work in accordance with prevailing and acceptable standards of scientific practice. Indeed, the experts cited by Mr. Landaluce, although they demonstrated their disagreement with the calculation method adopted by the LNDD, have not reversed the presumption that the analyses were in compliance with point 5.4.4.1.3 of the ISL. Therefore, the Panel finds that Mr. Landaluce has not proved that there was a departure from point 5.4.4.1.3 of the ISL.

c) The argument that the requested information was not provided to the cyclist or to his expert (point 5.4.7.3 of the ISL and of technical documents TD2004EAAS and TD2003IDCR)

80. Mr. Landaluce argued that he did not receive the information requested several times, by him as well as by Dr. de Boer, which would have made it possible to evaluate the analysis done by the LNDD.

81. The UCI indicated that RFEC correspondence dated 22 November 2005 shows that Mr. Landaluce received the totality of the documents relative to the A and B sample analyses. The UCI also argued that correspondence containing the requested information was sent directly by the LNDD to the RFEC. This correspondence was received safely by the RFEC which stamped it, despite the fact that the CNCDD decision indicates that no response from the LNDD was received.

82. In addition, Dr. de Boer indicated that he received on 29 August 2006 a document containing the evaluation of the retention times for the identification of the steroids in question in the B sample analysis. However, he noted that no information was communicated to him regarding mass spectral and identification data on the steroids involved in the A sample analysis. Therefore, Dr. de Boer's opinion was that there was a departure from point 5.4.7.3 of the ISL and technical documents TD2004EAAS and TD2003IDCR.

83. The Panel notes once more a divergence of opinion between the experts present at the Hearing. Indeed, Dr. Saugy indicated that the information necessary for the identification of these products were provided by the LNDD. This analysis by an expert who enjoys non-negligible experience in this field is quite plausible. Therefore, the Panel considers that Mr. Landaluce has not reversed the presumption that the LNDD complied with point 5.4.7.3 of the ISL and technical documents TD2004EAAS and TD2003IDCR.

d) The arguments that the values do not significantly differ from 3 delta units or more and that three aliquots should have been analyzed (technical document TD2004EAAS)

84. According to the technical document TD2004EAAS:

"The results will be reported as consistent with the administration of a steroid when the 13C/12C value measured for the metabolite(s) differs significantly i.e. by 3 delta units or more from that of the urinary reference steroid chosen. In some Samples, the measure of the 13C/12C value of the urinary reference steroid(s) may not be possible due to their low concentration. The results of such analyses will be reported as "inconclusive" unless the ratio measured for the metabolite(s) is below -28‰ based on non-derivatised steroid."

85. According to Dr. de Boer, this technical document requires that the values differ significantly from three delta units or more. In addition, since this is a threshold value, the ISL requires that three aliquots be analyzed, or as in the case in point, when only one aliquot is available, that it be analyzed three times.
86. As for Prof. de Ceaurriz and Dr. Saugy, their opinion was that triplicate sample measurements are not necessary and that such a requirement, which does not even exist, would on the contrary be problematic when the necessary urine volume is not available. They indicate that this is not a threshold analysis requiring the analysis of several samples.
87. The Panel notes once more that there is a difference in interpretation between the experts and considers that Mr. Landaluce has not reversed the presumption that the LNDD complied with technical document TD2004EAAS.

2. Alleged failures concerning the procedure followed by the LNDD

a) the argument that deadlines were not met (points 5.2.4.3.2.1 and 5.2.6.5 of the ISL)

88. Dr. de Boer claimed that the LNDD did not meet the deadlines described by points 5.2.4.3.2.1 and 5.2.6.5 of the ISL.

89. According to point 5.2.4.3.2.1 of the ISL:

"In those cases where confirmation of a Prohibited Substance, Metabolite(s) of a Prohibited Substance, or Marker(s) of the Use of a Prohibited Substance or Method is requested in the "B" Sample, the "B" Sample analysis should occur as soon as possible and should be completed within thirty (30) days of notification of an "A" Sample Adverse Analytical Finding."

90. According to point 5.2.6.5 of the ISL:

"Reporting of the "A" Sample results should occur within ten (10) working days of receipt of the Sample. [...] The reporting time may be modified by agreement between the Laboratory and the Testing Authority."

91. Dr. de Boer emphasized that the A sample results, which should have been reported within 10 working days of 14 June 2005, the date of receipt of said sample by the LNDD, were reported only 23 days later, i.e., 17 July 2005. Dr. de Boer also indicated that the B sample analysis was not done by the deadline of thirty days after notification of the A sample adverse analytical finding. Indeed, the A sample analysis result notification occurred on 28

July 2005. The LNDD proposed the date of 11 September 2005 for the opening of the B sample, a date which, upon request by Mr. Landaluce, was postponed to 21 September 2005, then rescheduled for 19 October 2005.

92. The UCI recognized that deadlines were not met, invoking *"laboratory overload, the complexity of the analysis and the vacation period."*
93. During the Hearing, the group of experts present declared that the delays had no effect on the analyses results.
94. In accordance with the rules relative to the method of establishing facts and presumptions, the Panel finds that Mr. Landaluce succeeded in reversing the presumption that the LNDD complied with points 5.2.4.3.2.1 and 5.2.6.5 of the ISL by demonstrating the existence of a departure. Such a demonstration, however, has only a purely theoretical effect, since the group of experts present at the Hearing observed that the departure observed could not be at the origin of the positive results of the A and B sample analysis. Therefore, the Panel concludes that Mr. Landaluce's adverse finding does not result from the departures from 5.2.4.3.2.1 and 5.2.6.5 of the ISL.

b) The argument that the analyst who did the analysis of the B sample was also involved in the analysis of the A sample (point 5.2.4.3.2.2 of the ISL)

95. According to point 5.2.4.3.2.2 of the ISL:

"The "B" Sample confirmation must be performed in the same Laboratory as the "A" Sample confirmation. A different analyst must perform the "B" analytical procedure. The same individual(s) that performed the "A" analysis may perform instrumental set up and performance checks and verify results."

96. Mr. Landaluce used as a basis the report of Dr. de Boer to claim that the analyst who did the analysis of the B sample was also involved in the analysis of the A sample, in violation of point 5.2.4.3.2.2 of the ISL.
97. Dr. de Boer indicated that this standard prohibits the same analyst from touching/manipulating both the A and B samples (*"touching the sample must be separate"*). [quote in English in the original document]
98. In this particular case, the report dated 11 June 2005 reveals that the analyst who did the analysis of the B sample did the following tasks in the A analysis: *package* [in English in the original document] at 4 degrees C, redissolve in acetonitrile and transfer to a vial, evaporate, redissolve in hexane and inject in the GC-MS.
99. The Panel President asked Dr. Saugy whether point 5.2.4.3.2.2 of the ISL prohibited the same analyst from touching/manipulating both the A and B samples. Dr. Saugy acquiesced in the following terms: *"I agree that it excludes any manipulation of the sample"*.

100. The Panel President then interrogated Prof. de Ceuriz to know whether the same analyst had touched/manipulated the A and B samples. Prof. de Ceuriz replied:

"Yes. It is clearly indicated. If you want, it is indicated in our chain of [custody]. There is no ambiguity on this. [The analyst] touched the samples in the A and touched the totality of the samples in the B. There is no ambiguity on this."

101. The Panel President then asked whether that constituted a departure from the ISL, to which Prof. de Ceuriz replied:

"Indeed. It is even openly in the laboratory documents. [...] with respect to the standard, that is true, she had contact with the sample".

102. Prof. de Ceuriz indicated that there had been 10% of "overlap between the two persons for workload reasons".

103. The group of experts present at the Hearing thus recognized that the analyst who participated in the two analyses did not limit herself to "performing instrumental set up and performance checks and verify results" and determined that there had been a departure from point 5.2.4.3.2.2 of the ISL.

104. In accordance with the rules relative to the method of establishing facts and presumptions, the Panel determines that Mr. Landaluce succeeds one more time in reversing the presumption according to which the LNDD would have acted in conformity with point 5.2.4.3.2.2 of the ISL, by demonstrating the existence of this departure. The consequences this time are decisive.

105. It was not demonstrated that this was not at the origin of the adverse finding, nor that it was. It was however incumbent upon the UCI, according to article 18 of the UCI Anti-doping Rules, to demonstrate that the departure from the ISL was not at the origin of the adverse finding, but this was not done. The UCI merely indicated in its appeal brief that:

"And even if there had been a departure—quod non—this couldn't have led to the adverse analytical finding, unless it is established that [the analyst] committed an error which caused the adverse analytical finding, quod non."

106. Also during the Hearing, the UCI simply noted:

"As for the departures from the ISL which were brought up, I believe I can conclude that if they took place, they are not significant and are certainly not at the origin of the result."

107. It was indeed for the UCI to demonstrate that the failure to meet point 5.2.4.3.2.2 of the ISL was not at the origin of the adverse finding. To the extent that the UCI did not succeed in doing so, the Panel's only possible conclusion is to exonerate Mr. Landaluce.

108. It is true that a decision pronounced on this question of the double involvement of the same analyst in examining A and B samples, in the case of Wang Lu Na and others versus FINA (TAS 98-208, decision dated 22 December 1998, Wang Lu Na and others versus

FINA) upheld the suspension of four swimmers. However, what that decision brings to the needs of present case is very marginal, for three reasons: Firstly, the applicable regulation is different. Then, the decision expressly indicates (*paragraph 5.22*) that the role played by the analysts in question was not clearly established: the arbitrators declared that they were "*unpersuaded*" by the argument according to which the analysts "*were involved in anything other than the tests of the controls*" as opposed to "*A samples themselves*". [quotes in English in the original document] In contrast, in the case in point, as demonstrated previously, the analysts who manipulated the A and B samples are one and the same. Finally, the swimmers' representatives had, by their signatures, recognized that the procedure described by the FINA regulation had been respected by the laboratory. In the case in point, the UCI did not follow up on presenting evidence that Mr. Landaluce had approved the procedure that was followed. [French grammar questionable]

109. Although aware of the imperatives of costs and organization faced by laboratories, the Panel must watch over the respect of fundamental rules, considering the implications that its decision could have on the reputation, and therefore, the career of the athlete, if a disciplinary sanction were to be pronounced against him.
110. The Panel is well aware that the standard which requires that a different analyst analyze the B sample has been the subject of intense discussions between WADA and laboratory directors. The latter claim that this rule unreasonably complicates laboratory operations, and yet it has not been demonstrated that it brings additional protection to the athletes tested. Indeed it would be unrealistic to require that the same analyst conduct the totality of an analysis from beginning to end. In fact, the analyses for certain substances can last several days during which processes are mechanically carried out. The analysts carry out numerous tasks, shifting from one to the other, so that several analyses can be done simultaneously. If it is conceivable to require of a large laboratory with a staff of 50 to 100 to organize the work so as to exclude from the analysis of the B sample the analyst who analyzed the A—even though this constitutes a non-negligible complication factor which the laboratories would rather be spared—such a requirement would constitute a major complication factor for a laboratory of smaller size.
111. It is virtually impossible to prove a negative fact, in this case that the involvement of the same analyst in both analyses did not affect the result. Therefore certain laboratory directors consider this rule too rigid; in reality, sufficient protection of the athletes is already ensured in that the system of identification of samples by codes ensures that their identity is not known to the analysts.
112. This reasoning, although rational and plausible, fails before the CAS for a very simple reason: the arbitrators do not create the rules, they apply them. This is all the more true because the authors of the antidoping regulation kept the rule which requires another analyst for the analysis of the B sample, even though they had heard the comments of the laboratory directors. The rules can certainly be modified or refined, but such is not the role of the CAS.

119. Articles R64.4 and R64.5 of the Code state the following:

"At the end of the proceedings, the Court Office shall determine the final amount of the cost of arbitration, which shall include the CAS Court Office fee, the administrative costs of the CAS calculated in accordance with the CAS scale, the costs and fees of the arbitrators calculated in accordance with the CAS fee scale, a contribution towards the expenses of the CAS, and the costs of witnesses, experts and interpreters. The final account of the arbitration costs may either be included in the award or communicated separately to the parties."

"The arbitral award shall determine which party shall bear the arbitration costs or in which proportions the parties shall share them. As a general rule, the award shall grant the prevailing party a contribution towards its legal fees and other expenses incurred in connection with the proceedings and, in particular, the costs of witnesses and interpreters. When granting such contribution, the Panel shall take into account the outcome of the proceedings, as well as the conduct and the financial resources of the parties."

120. In this case, the UCI appeal is dismissed and the decision being appealed must be confirmed. This arbitration being at no cost to the parties, since it is a disciplinary case of an international nature, it is necessary to determine whether and to what extent Mr. Landaluce and the RFEC have a right to an indemnity for their attorneys' costs and for the other costs relative to the present arbitration proceedings. After having duly considered the overall circumstances of the case, particularly the large number of futile arguments invoked by the defendants, the Panel considers it equitable to let each party pay the costs incurred in this procedure.

VII. CONFIDENTIALITY

121. According to article R59 paragraph 6 of the Code of Sports-related Arbitration:

"The award, a summary and/or a press release setting forth the results of the proceedings shall be made public by the CAS, unless both parties agree that they should remain confidential."

122. Mr. Landaluce indicated that he wished for the proceedings to remain confidential and that no press release setting forth the proceedings be made public by the CAS.

123. The UCI indicated that the proceedings initiated against Mr. Landaluce were already known to the public, since they have been the subject of a press release by the CAS.

124. During the Hearing, the UCI, Mr. Landaluce and the RFEC did not reach agreement on the confidential or non-confidential character of the present proceedings. Under these circumstances, the CAS will be able, if it deems it appropriate, to make public a summary and/or a press release setting forth the results of the proceedings.

ON THESE GROUNDS

The Court of Arbitration for Sport rules that:

1. The Court of Arbitration for Sport is competent to rule on the appeal submitted by the Union Cycliste Internationale.
2. The appeal submitted on 26 June 2006 by the Union Cycliste Internationale against the decision rendered on 5 May 2006 by the Comité Nacional de Competición y Disciplina Deportiva de la Real Federación Española de Ciclismo is dismissed.
3. The award is rendered at no cost, except for the Court Office Fee of 500 Swiss francs paid at the beginning of the proceedings by the Union Cycliste Internationale, which shall be kept by the CAS.
4. Each party shall bear the costs of its attorneys and other costs associated with the present proceedings.

Lausanne, 19 December 2006.

Testing urine for drugs

D. Catlin, D. Cowan, M. Donike, D. Fraisse, H. Oftebro and
S. Rendic

*Departments of Medicine and Pharmacology, University of California, Los Angeles, UCLA Medical Center,
650 Circle Drive South, Los Angeles, CA 90024 (USA)*

Key words: FCC; Urine testing; Doping; Gas chromatography-mass spectrometry; Drug abuse;
Drug testing

I. Introduction

The rising demand for drug testing comes from societies' pressures to stem the spread of substance abuse and to provide greater protection to their members. In response to this demand urinalysis testing programs have been implemented by a wide variety of organizations such as business and industrial employers, the transportation industry, police and fire departments, the military and sports [1–7]. The drugs most commonly tested for are marijuana, cocaine, amphetamines and narcotic analgesics. Some programs also test for benzodiazepines, barbiturates and phencyclidine.

One common denominator is the widely accepted notion that drug testing will identify the primary offenders. The extent to which this objective is achieved is most appropriately addressed by specialists in behavioral medicine and sociology. The scientific basis for urinalysis programs is in the domain of clinical and analytical chemistry.

The analysis of body fluids for drugs takes place in two distinctly different environments: the medical model and the penalty model. In the former and in the context of patient care, the physician requests the test and the patient is both fully cooperative with the sample collectors and highly motivated to provide the ideal

sample. In the latter case the request usually comes from a non-medical authority and it may not be in the best interest of the individual to submit a valid sample. In the medical model the information obtained from the test is used to assist the physician in the care and management of the patient. In contrast, in the penalty model the results are used to impose some penalty to the individual. This fundamental difference together with legal imperatives has broad implications for the overall design and implementation of a drug testing program.

Although it may seem counter-intuitive, testing in the penalty model is far more demanding and difficult compared to the medical model. For example, if a physician sends a sample from an unconscious patient to the laboratory for a rapid screen and, 1 h later, the report is positive for opiates by immunoassay, the physician will use this information to tailor treatment to the opiate overdose as opposed to say the barbiturate overdose. It is relatively unimportant to know if the primary drug is morphine or codeine because the clinical implications are very similar. In contrast, if the urine came from a pre-employment screening program, it would be of utmost importance to know if the positive test was due to the consumption of heroin, a dangerous and illicit drug, or codeine, a drug which is widely available and commonly prescribed for pain. In fact since urinary morphine could arise from the ingestion of morphine, heroin, or codeine the complete analysis of this sample requires a specific and quantitative analysis for all metabolites of all three substances. Furthermore this type of analysis virtually requires gas chromatography-mass spectrometry (GC-MS), a technique which is inherently difficult, labor intensive and expensive. Thus the complete analysis of a complex sample is generally beyond the traditional scope of hospital or clinic based clinical chemistry laboratories and serves to emphasize that the clinical chemist who wishes to extend his practice to drug testing must be prepared for a substantial increase in analytical instrumentation and technical training. Further amplification of this point appears in numerous recent publications and reviews [3,4,8].

Additional factors which must be considered in the testing with penalties model include constant scrutiny by the legal community, the activity of regulatory agencies, scrupulous attention to chain of custody both within and without the laboratory, space allocation to provide for specialized functions and security and development of substantial knowledge regarding the pharmacology, pharmacokinetics and metabolism of the substances. In order to accommodate these considerations the traditional laboratory must reorganize administrative procedures, job descriptions, security, laboratory protocols and space allocation.

Urine testing of sportpersons (doping control) differs from that of employees in that the main reason to test is to maintain fair play by prohibiting the use of performance-enhancing drugs, as opposed to protecting safety or productivity on the job by prohibiting street drugs. In marked contrast to testing for the so called 'drugs of abuse', the menu of drugs tested for by sport authorities is both comprehensive and includes several classes of substances [1,9]. Some banned substances are also produced endogenously (e.g. testosterone) and in the case of several substances the ban is based on quantification. Detection of the administration of exogenous testosterone requires special testing techniques [8,10,11].

The current list of substances banned by the International Olympic Committee

consists of six groups [8], i.e. the stimulants where several classes are found such as the psychomotor stimulants (ex: amphetamine), the sympathomimetics, (ex: ephedrine), and the analeptics (ex: strychnine, caffeine). The other groups are narcotics, anabolic steroids, beta-blockers, diuretics and certain peptide hormones. This classification is based on the expected effect of the drugs on the athlete as opposed to their chemical structure and properties.

II. Regulatory Considerations

Legal review can be expected [12], therefore laboratory directors should be familiar with the relevant local, national and international laws. In general such reviews are designed to find fault with any aspect of the system and in particular the authority to test, provisions for individual consent to undergo testing, collection procedures, chain of custody, sample chemistry, instrument maintenance, tuning and calibration records, quality control, the analytical data consisting of chromatograms and spectra, sample storage, qualification of laboratory personnel, confidentiality and appeal process. Laboratories are advised to review carefully the documents which describe the authority to test and the details of the client's protocol. The best defense for an unfavorable legal decision is excellence in analytical chemistry together with a complete set of written procedures covering all aspects of the testing program and documentation showing that all procedures were followed.

Various countries and scientific organizations either have produced or are in the process of preparing guidelines to regulate drug testing laboratories [2,4-6]. These are designed to protect the person tested ('testee') by improving the quality of the work product by emphasis on quality assurance, quality control, proficiency testing and documentation. In some countries the guidelines are incorporated into accreditation or certification programs [5]. Consumers of laboratory services are encouraged to use only those that are certified or accredited.

III. Sample Collection Procedures

Prior to urine collection the testee is offered the opportunity to declare all medications and related substances taken recently. This information becomes part of the documentation, and in the event of a positive test and legal action, it is used by the certifying scientist to evaluate the possibility of analytical interferences or inadvertent use of a banned substance.

It is essential to ensure that the urine tested is authentic urine from the designated individual. Experience has shown that some individuals will attempt to evade submitting authentic urine by techniques such as concealing bladders and tubing under their clothing and even introducing 'clean' urine into their bladder just before the test [13]. To help exclude these measures and other forms of substitution, the testee should remain under the constant supervision of at least one member of the drug testing team from the time of notification to the time of urination. Next the drug testing official must verify the identity of the testee by requesting a passport, driver's license, or otherwise accepted document with photograph. Finally the actual urination should be directly observed by a drug testing team member of the same gender

(cf. Ref. 15). Some organizations go to further extremes and require removal of all clothing. Others do not directly observe urination, but use temperature-sensitive containers [5].

To ensure sample integrity, the urine collection containers should be individually sealed. The testee is given the opportunity to select any container which is used to collect or ship the specimen. No one but the testee should handle the urine in the container and/or the bottles until they are sealed. The testee and officials all sign a declaration that protocol was followed to their satisfaction. The laboratory should not know the identity of the testee, therefore urine samples are forwarded to the laboratory identified only by a number. The organization retains the confidential master code which links each number to an individual's name. To exclude all varieties of sabotage, the collection area should be secure and have restricted access such that no unauthorized person can enter.

Because there are manipulations which affect renal excretion and the urinary concentrations of the forbidden drugs, some drug testing programs require that the pH and specific gravity be within a specified range and may require holding the testee to provide additional urine that fulfills the criteria. For example the excretion of many nitrogen-containing drugs depends on urine pH. If the urine is alkaline, certain stimulants are excreted less, therefore a testing program may not accept a sample if the pH is 7.5 or greater. Another example is that of dilution by diuretics or excessive liquid intake, such that 1.005 may be the lowest acceptable specific gravity. These parameters may be measured with a dipstick on the urine remaining in the container after all bottles have been sealed, thus excluding the possibility of contamination by the dipstick. In some drug testing programs the specific gravity is not measured at the collection site. Some laboratories measure specific gravity and/or creatinine before proceeding with the analysis and, they may use this data to determine if the sample is valid. The laboratory must receive a sufficient volume to complete all tests. Most protocols define a minimum acceptable volume.

For the additional protection of the testee, many organizations require the division of the urine sample into two parts, A and B, to be sealed individually. The laboratory ordinarily receives both, saves the B intact, analyzes the A and reports the results to the organization.

IV. Chain of Custody

To ensure that the urine tested suffered no contamination, tampering, or mislabeling, the chain of custody begins at the collection site and ends with the final report. The sample is handled at first only by the testee until sealed, then by collection site officials, transportation personnel and laboratory technicians. The control system must guarantee integrity of the specimens from the moment of submission of the urine until the conclusion of the analysis. Each transfer must be documented, including within-laboratory transfers. Experienced couriers are recommended for the transportation of samples to the laboratory. A chain of custody form and manifest are initiated at the collection site. The laboratory checks the custody form, examines the package for evidence of tampering and then accepts custody of the package. After opening the package the samples are inspected individually and checked

against the manifest. At this juncture the laboratory initiates its internal chain of custody. Once the chain is initiated, only qualified laboratory personnel may work with the sample and no unauthorized visitors may be in the work area. On request the laboratory must be able to give exact documentation on details such as where a certain sample was located at a given time and the identity of the person handling the sample at the time in question. The samples should be stored at +4°C or colder in a locked area.

V. Analytical Approach

Because of the consequences to lives, careers and reputations which follow reports of positive analytical findings, urinalysis for banned drugs must be done using methods that give indisputable evidence. A screening test divides the samples into two categories: a large group of analytically negative samples, and a smaller group that requires further analysis (confirmation test). In the latter case, the screening data indicate that a banned substance or its metabolites may be present and provide tentative identification. The principles of decision theory have been used to calculate the predictive value of screening and confirmation tests [14]. Confirmatory tests are time-consuming, complex and have one principal goal: they provide data for the final, unequivocal identification of the banned substance or metabolites. In addition, confirmatory tests are used to confirm the identity of the biological sample (e.g. that the urine used for the second analysis is the same as the one used for the first analysis), to exclude clerical errors and to confirm that the analysis is reproducible.

A. Sample preparation

Glassware must be scrupulously clean. False positive results have been traced to soap residues [4]. To avoid contamination with phthalates nothing but glass or teflon should come in contact with the sample. The purity of the solvents and reagents should be appropriate to the analysis. Sample preparation is specifically designed in an attempt to optimize the detection of each chemical class of substance. If the drugs and metabolites are excreted as conjugates (sulfates or glucuronides), a hydrolysis step is necessary prior to extraction. Compared to acid hydrolysis, enzymatic hydrolysis is usually less destructive to deconjugated products. Polar compounds containing hydroxyl, keto, acid, or amine functions are usually converted to less polar and more volatile derivatives. The most common derivatizations are trimethylsilylation, trifluoroacylation and methylation. Many unconjugated nitrogen-containing compounds may be extracted with diethyl ether at pH > 12, separated by GC and detected with a nitrogen phosphorus selective detector (NPD). Acidic compounds, e.g. barbiturates and benzodiazepines, require extraction at appropriate acidic pH. Amphoteric compounds, such as morphine, are extracted most efficiently at their isoelectric point with polar solvents such as ether and propan-2-ol. Conjugated nitrogen compounds (beta-blockers, opiates, hydroxylated phenylalkylamines) may be extracted after hydrolysis with diethyl ether, derivatized by trimethylsilylation and/or trifluoroacylation, separated by GC, and detected by NPD. Many diuretics are acidic compounds and are extracted at pH < 2. Because

of their low volatility and thermolability they are not amenable to GC analysis without derivatization. Diuretics may be screened for by HPLC with UV detection or by GC and/or by GC-MS.

B. Screening tests

Most of the screening tests performed currently are based either in immunoassay or chromatographic techniques.

Immunoassay (IA). This is the most commonly employed screening test [3]. A wide variety of IA-based methods have been developed and automated. One common feature of IA is the utilization of antibodies with specificity for the drug and/or metabolite and closely related substances. Since the antibodies cross-react with substances which are similar in structure to the target substance, the analytical results are neither unambiguous nor strictly quantitative and must be confirmed. A variety of interferences have been described (e.g. Ref. 15).

Chromatography. The different kinds of chromatography (e.g. TLC, GC, LC) are basically separation techniques used to resolve complex biological mixtures. With appropriate physico-chemical detection and with strict standardization of experimental parameters identification and quantitation can be achieved.

Thin-layer chromatography (TLC) is a common screening test for drugs of abuse. After an extraction at controlled pH, a tentative identification of drugs can be made based on physico-chemical characteristics (R_f values) and color reactions.

High performance liquid chromatography (HPLC) is ideally suited for thermolabile and polar substances. It is most commonly used in a modification known as reverse phase chromatography. The conditions may be adjusted to solve a wide range of analytical separation problems. The available choice of detection — UV/visible, fluorescence, electro-chemical, chemical detection and MS — will allow sensitive group or even substance detection.

Gas chromatography will separate thermostable drugs that are sufficiently volatile to be eluted from the analytical column. Fused silica capillary columns provide the necessary high resolution to separate extremely complex mixtures or biological matrices. Polar substances need derivatization prior to GC. With element-specific detectors (e.g. NPD) or in combination with a MS, selective and sensitive detection of a wide variety of drugs is possible.

C. Confirmation tests

In confirmation tests the unknown and the standard undergo simultaneous sample preparation from extraction to derivatization followed by analysis. Evidence of the presence of a compound includes multiple measures of similarity, such as instrumental analysis data and relative amounts (or concentrations) of multiple urinary metabolites.

Although several approaches may be used to confirm the presence of substances in urine, gas chromatography-mass spectrometry (GC-MS) is currently the method of choice for unambiguous identification. It is the combination of two techniques, where the MS is used as a detector for the GC. GC separates the components of a

mixture and introduces them one by one into the mass spectrometer, which records a mass spectrum or 'fingerprint' of each isolated component. Properly performed GC-MS analysis unequivocally identifies the compound, not just the drug class or chemical family. For the confirmatory analysis an extract from a new aliquot of urine is prepared using the same protocol as for the screening procedure, or using an appropriate alternative.

GC provides two elements of identification: RT and RRT. The GC retention time (RT) of a compound is the time elapsed between injection of the extract into the inlet and appearance of the compound at the outlet. It is reproducible under equal operating conditions. If an unknown has the same RT as the standard it may be the same substance or it may be a different one. If an internal standard is present in both the unknown extract and the standard extract, one can calculate the relative retention time (RRT) as: $RT(\text{compound})/RT(\text{internal standard})$. The RRT is more reproducible than the RT. If an unknown has a RRT different from the RRT of the standard it is a different substance. The main determinant of RT and RRT is column polarity. Another means of characterizing a substance is retention index as originally described by Kovats [16] and later modified and improved by various authors [17]. This is useful because it allows comparison with the scientific literature.

Mass spectrometry is a very powerful technique but many of its capabilities cannot be realistically applied on a large scale for routine work. The two most frequently employed ionization techniques are electron impact and chemical ionization; The electron impact mode is commonly used to obtain a full scan. Chemical ionization is particularly useful to confirm the molecular weight of a substance.

Most mass spectrometers can give an interpretable full scan spectrum with less than 1 ng of material. However even greater sensitivity can be achieved by monitoring only a few characteristic ions of the suspected compounds in the selective ion monitoring (SIM) mode. Data collected in the SIM mode may not be considered as sufficient proof of positive results by the most demanding chemists, nevertheless SIM data are commonly presented to document a positive finding and this is acceptable to many regulatory bodies and scientists. If the analysis is based on SIM data, the certainty is greatly enhanced if more than one characteristic substance is found in the sample, e.g. the parent drug and a metabolite. In addition if SIM data are used it is important to demonstrate equivalence between ion ratios for the sample and a standard. Furthermore one should demonstrate that the ion of interest dominates its region by monitoring the ions immediately preceding and following it. This shows that the pertinent ion is not derived from the preceding ion and that the following ion is present in the proper ratio to the pertinent ion.

Unambiguous identification is accomplished by matching the RRT and spectra of the identified substances with those of authentic reference standards concurrently extracted from spiked urines (positive quality control) or certified positive cases. The reference spectra are contained in a mass spectral library. Such a library should be developed in each laboratory by analyzing derivatized compounds or their metabolites under comparable operating conditions. If reference standards of metabolites are not available, clinical studies may be performed by administration of the parent drug to man followed by timed urine collections and the resulting urines used as positive quality control samples.

VI. Quality Assurance

Quality assurance is '....planned and systematic actions necessary to provide adequate confidence that a product or service will satisfy given requirements for quality' [18,19]. Quality assurance encompasses quality control (QC) and quality assessment. The overall aim is to ensure that the analytical results are of sufficient accuracy for their intended application.

The goal of quality assurance in drug testing is to minimize and document the probability of false positive and false negative results, as well as to document compliance with good laboratory practices (GLP) and the requirements of regulatory agencies. Quality is a team work ethic which materializes in various forms in all aspects of the work. Quality assurance may be implemented by a designated senior scientist and manager. Some laboratories refer to such individuals as QA officers.

In the context of large drug testing programs, for example those operated by governments, sport authorities and military establishments, quality is monitored by accreditation and proficiency testing programs that establish requirements of competence and equivalency for the protection of the organization conducting the testing and of the individuals tested. Usually the requirements cover personnel needs and qualification and material resources (e.g. instruments) and analytical capabilities specific to a finite list of substances at specific concentrations. Compliance is documented by on-site inspection and written reports. Failure to comply results in immediate restriction of the work. The proficiency testing aspect of the program utilizes biological samples prepared to contain known amounts of specific banned substances. The samples are sent to the laboratory in the blind (unknown to the laboratory) or open (known to the laboratory) mode. Proficiency testing programs document the strengths and deficiencies of the participating laboratories and provide objective data for between laboratory comparisons [20,21].

Critical review of QC data and optimization of QC design should be a constant and integral part of the ongoing work in a drug testing laboratory. Each laboratory maintains written Standard Operating Procedures (SOP) which describe each protocol in unique, detailed and mandatory terms. Technicians are expected to adhere to the SOP. Laboratories should utilize internal QC biological samples either blind (to those doing the analyses) or open. Good quality control procedures monitor all possible sources of error and provide for rapid isolation of the problem. At least ten percent of the samples in a batch are related to QC. Such procedures assess: clerical accuracy, sample preparation recovery, chromatographic performance, mass spectral sensitivity, overall assay detection threshold and precision in quantitation. Examples of independent cross checks are overlapping successive batches of QC samples or requiring verification by two persons. Record-keeping should include QC data and the description of measures taken to correct actual problems.

VII. Interpretation of Test Results

A. Pharmacokinetics

In theory complete knowledge of the pharmacokinetics of a drug enables a precise prediction of the concentration of drug in urine at various times after drug ad-

ministration. In practice, however, many relevant variables cannot be known and the predictions become relatively gross estimates. Nevertheless knowledge of the principles of pharmacokinetics enables the person responsible for interpreting the results of a drug test (the interpreter) to provide the most complete and accurate report and assessment.

The concentration of drug in plasma at various times after intravenous administration drug administration is determined by the dose and clearance (a pharmacokinetic variable that encompasses half-life and volume of distribution) [22]. The concentration in urine may also be estimated if clearance of drug and water are known. If the drug is orally administered the model must include bioavailability and the rate of absorption. Sophisticated pharmacokinetic models can also account for multiple and variable doses and dosage intervals [22,23]. Drugs with long half-lives and/or large volumes of distribution may be detectable in small amounts in urine for months. Examples of studies which provide useful pharmacokinetic data are: marijuana [24–26], cocaine [23,27], amphetamine [28]. Reviews [3,6,8] provide additional references.

Many of the relevant variables are rarely known therefore the interpreter evaluates the pattern of excretion of drug and metabolites as determined by clinical studies. One must consider the sensitivity of the assays since it is a major determinant of detection times. Clearly a large dose will result in a positive test for a longer time than a small dose. Multiple closely spaced doses will result in drug accumulation, an increase in total body burden and longer detection times. For example urine collected within the first few hours after cocaine administration contains both cocaine and benzoylecgonine, while urine collected several hours later will not contain detectable amounts of cocaine [27]. The principal metabolite of tetrahydrocannabinol (11-nor- Δ^9 -tetrahydrocannabinol-9-carboxylic acid) is usually detectable for 1 or 2 days after single exposure, however, multiple exposures may lead to a positive test for 2 or more weeks after cessation [25]. In addition passive exposure to marijuana smoke may result in sufficient absorption to result in detectable amounts of marijuana metabolites in urine [29].

Single doses of many anabolic steroids result in a positive test for 1–3 days, while multiple doses result in positive tests for many days or weeks. Steroids that are formulated in oil and administered by injection may be detectable for several months.

B. Drug metabolism

The majority of drugs are lipophilic and undergo oxidative metabolism resulting in more polar, ionizable metabolites which are either eliminated as such or after conjugation. Alterations in the rate and extent of drug metabolism influences the elimination half-life and clearance of drugs and as a consequence, the concentrations of parent drug and of metabolites in blood and in urine.

About 90% of all oxidative metabolic reactions are catalyzed by the cytochrome *P*-450 enzyme system present in endoplasmic reticulum of liver cells, therefore this enzyme system plays a central role in the metabolism of lipophilic drugs such as stimulants, beta-blockers, steroids, opioids and other drugs.

Comprehensive knowledge of the metabolism of each banned substance is essential to the interpretation of drug testing results. For example the ingestion of some

types of poppy seeds results in morphine in the urine [30]. Since morphine is a major metabolite of heroin, the detection of morphine is compatible with administration of heroin or the ingestion of poppy seed products. One way to clarify this situation is to analyze the urine for 6-monoacetylmorphine, which is a metabolite of heroin and not a metabolite of morphine and not found in poppy seeds [31].

C. Drug interactions

The best studied drug interactions known to markedly influence drug or metabolite concentrations in body fluids are inductions and inhibitions of enzymatic reactions catalyzed by cytochrome *P*-450. Induction results in a decrease in half-life (increase in clearance) and more rapid elimination from the body. Furthermore induction often changes the pattern of metabolite elimination. Substances well known to induce the *P*-450 system include drugs such as barbiturates, glutethimide, carbamazepine, ethanol and phenytoin (hydantoins) and environmental chemicals such as polycyclic aromatic hydrocarbons (3-methylcholanthrene, benzo[*a*]pyrene) and polychlorinated aromatic hydrocarbons (polychlorinated biphenyls).

The inhibition of oxidative drug metabolic reactions by relatively unspecific inhibitors like cimetidine, chloramphenicol or sulfonamides will increase drug half-life and increase blood levels of the inhibited drug. This results in a decrease in the concentration of both parent drug and metabolites in urine and therefore the ability to detect drug use. Furthermore, the individual may experience enhanced drug effects and/or toxicity.

A number of clinically significant drug interactions resulting from concomitant administration of cimetidine with drugs such as caffeine, beta-blockers, barbiturates, morphine and ethanol have been described [32]. The mechanism of inhibition is an interaction of cimetidine with the heme iron in cytochrome *P*-450 [33]. Like cimetidine, the anabolic steroid stanozolol interacts with cytochrome *P*-450 and is a potent inhibitor of cytochrome *P*-450-catalysed reactions [34]. Depending on the particular isoenzymes that are inhibited stanozolol could alter the elimination of other anabolic steroids.

Interactions involving drugs that influence the pH and water metabolism of the body alter the excretion rates of many banned drugs. The urinary excretion of many drugs is markedly influenced by urine pH [22,28,35,36]. The excretion of basic drugs (e.g. amphetamine) decreases as the pH of urine increases. Bicarbonate has been used to rapidly change the excretion rate of basic drugs and thereby reduce the likelihood of a positive test. Similarly the excretion of acidic drugs (e.g. some diuretics) is retarded by low urinary pH. Other drugs influence the excretion of anionic substances. For example, probenecid and related substances temporarily decreases the tubular excretion of anabolic steroids, penicillins, indomethacin and others. Some drug users attempt to avoid detections by adding adulterants directly to urine [15].

The state of hydration of an individual, by its effect on the water content of urine, markedly influences the concentration of drugs. Indeed excessive intake of fluids is commonly used to dilute the urine and lower the concentration of drugs. Similarly diuretics have been used to rapidly dilute the urine. Some testing programs routinely measure the specific gravity of urine to provide some insight into this problem.

Measuring the urinary creatinine and reporting the concentration of drug per mg of creatinine is another technique of factoring for the effect of dilution.

Consideration of the pharmacokinetics, pharmacodynamics, metabolism and drug interactions leads to the conclusion that it is very difficult to answer the question of whether or not an individual was under the influence of the drug at the time the sample was taken. Given sufficient analytical data and using tenable assumptions, the interpreter may be able to offer a reasonable opinion on this question.

VIII. Documentation of Results

The analytical report should be limited to statements of fact so as not to be confused with opinion. Therefore, where necessary, two distinct documents should be provided. The analytical results and other observations are normally documented in the analytical report, whereas matters of opinion should appear in a letter which accompanies that report.

A. Content of the analytical report

The analytical report must provide sufficient information to enable the recipient to identify the individual(s) from whom the sample(s) described in the report originated. To avoid transcription errors all code numbers should be checked and double-checked by two persons. A complete description of the testing occasion is the best way to prevent such errors.

The report will contain chain-of-custody information including the date and time of arrival of the samples in the laboratory so that the analytical report may be linked to other chain-of-custody documentation. The integrity of the samples will be documented by including statements that the samples were sealed and, where appropriate, recording the seal numbers or other identifying features. The type(s) of assay performed must be stated either explicitly or, where an accepted protocol has been established, implicitly.

Qualitative results. Either the absence of the substances or the presence of the chemical entities identified in the individual samples must be clearly stated. Examples of appropriate statements might be:

'No substance banned by the [insert name of organization] was found in any of the samples'

or

'The sample coded 2345A was found to contain [insert proper name] as described in the details attached. No substance banned by the [insert name of organization] was found in any of the other samples.'

The proper name should be the IUPAC name of the chemical entity identified or if the identified substance is a parent drug (as distinct from a metabolite of that drug) then the International Non-Proprietary Name (INN) might be used instead. Under some circumstances the use of the IUPAC name is cumbersome. In these cases, it may be convenient to use the INN.

It is customary for supporting data to be included such as chromatographic data and GC-MS data obtained from the sample specified and, in addition, data on corresponding reference standards (or reference urines obtained from suitable excretion studies). The reference data would normally be obtained after the specified sample has been analyzed with suitable precautions to exclude the possibility of contamination. A sufficient description of the analytical methods used should be presented to enable the chromatographic and mass spectral data to be interpretable.

Quantitative results. Many drug testing programs define a particular concentration of drug or metabolite as the dividing value for reporting a urine result positive or negative. This value, which is often referred to as the cutoff, represents an administrative decision on the part of the program. The cutoff may be considerable greater than the detection limit (lowest concentration that can reliably be detected) of the assay. Cutoff concentrations may apply to the screening test and the confirmation test. For example, the IA cutoff for cocaine in the US Department of Defense program is 300 ng/ml and the corresponding cutoff for benzoylecgonine by GC/MS is 150 ng/ml [4]. This leads to the terminology 'analytical positive', which refers to a sample containing detectable amounts of drug, but which is reported or considered negative by the program.

If the quantitative results are greater than the cutoff, at a minimum the sample is reported positive, or more informatively, substance detected. It is more informative to report that the substance was detected at a concentration greater than the cutoff. Clearly, the concentration must exceed the cutoff by more than the experimental variation. In all other cases, the mean of the measured values should be stated together with an estimate of the precision, e.g. relative standard deviation (coefficient of variation) or confidence interval for the measurements.

If quantitative results are being reported and the substances under investigation are present in concentration which are less than the cut-off value but greater than the detection limit, then the results should indicate that fact in the format of: substance detected, not greater than X (where X is the cutoff defined by the program). In this case the sample is positive by analytical criteria, but negative by administrative criteria. It is informative to report the detection limit of the laboratory for that specific substance at that time. Do not report the substance as being not present or even not detected.

B. Supplemental information and opinion

Avoid including in the analytical report irrelevant findings since they might be misinterpreted or confusing. Similarly, do not include in the analytical report the finding of endogenous or even ubiquitous substances except and unless the analytical protocol so demands, e.g. where concentration limits are imposed and/or where administration of a substance which is indistinguishable chemically from an endogenous substance is suspected, e.g. testosterone.

Any additional information or statements of opinion may be expressed in a separate document, e.g. a covering letter. Examples of information which might be relevant include:

- (a) Highlighting a declaration which has accompanied the samples such as a

medical certificate, or drug declaration by the individual who has provided the sample where this is relevant and the laboratory data supports that statement.

(b) Where a chemical entity has been found and detailed in the analytical report and the presence of this substance is considered to be a characteristic metabolite of a present drug subject to control, then an appropriate statement should be given with supporting literature references, e.g. '11-nor-delta-9-tetrahydrocannabinol-9-carboxylic acid is a metabolite of THC' or 'the presence of 19-norandrosterone (3-alpha-hydroxy-5-alpha-estran-17-one) is considered to be evidence of the administration of the anabolic steroid nandrolone'.

No statement about the intent of the individual providing the sample should be made. The laboratory should restrict its report to the sample provided (other than as described above) It is generally unwise to make any unsolicited comments about the time when the last administrations might have occurred since there is unlikely to be any supporting information, e.g. dose taken, size of individual, metabolic characteristics of individual available to the laboratory at that time.

IX. Acknowledgements

We thank the following organizations and entities for supporting this work: Centre National de la Recherche Scientifique, Service Central D'Analyse (FR); the United States Olympic Committee, the National Collegiate Athletic Association (USA), the Norwegian Confederation of Sport (NOR) and the British Sports Council (GBR).

LABORATORY INTERNAL CHAIN OF CUSTODY

There are two parts involved in the chain of custody for an individual *Sample*. Both components must be maintained in the Laboratory as part of its testing records. The external record is initiated at the collection site and ensures that the *Samples* and the results generated by the Laboratory can be unequivocally linked to the athlete. The Laboratory Internal Chain of Custody records are maintained within the Laboratory to record the testing process and the location of the *Sample* during testing.

The Laboratory Internal Chain of Custody is documentation (worksheets, logbooks, forms, etc.) that records the movement of *Samples* and *Sample Aliquots* during analysis. A Laboratory Internal Chain of Custody does not require a separate form. Within the Laboratory, the Laboratory Internal Chain of Custody shall be a continuous record of individuals in possession of the samples or *Sample Aliquots*. When not in an individual's possession, it should be documented that the *Sample* or *Aliquot* is within a controlled zone (Ref *International Standard* for Laboratories 5.4.3.2). The *Sample* or *Aliquot* must be in an individual's possession when in an uncontrolled or unsecured area of the laboratory. The entry into the Laboratory Internal Chain of Custody should be completed at the time that any change of possession occurs. The Laboratory Internal Chain of Custody must contain the name or initials of the individual, date of transfer, and the purpose of the transfer of possession. The individual's complete signature/name should appear in the documentation at least once.

A chain of custody is required for both "A" and "B" *Sample* bottles and every *Aliquot* prepared for a testing procedure. In the case of *Samples*, the Laboratory Internal Chain of Custody should record all movement from receipt in the Laboratory through storage and sampling to disposal. In the case of *Aliquots*, the Laboratory Internal Chain of Custody should record all movement from preparation through analysis. When a group of *Samples* is aliquotted for testing, a batch *Aliquot* Laboratory Internal Chain of Custody document for screening and/or confirmation may be used in lieu of an individual *Aliquot* Laboratory Internal Chain of Custody.

Any forensic corrections that need to be made to the document should be done with a single line through and the change should be initialed and dated by the individual making the change. No white out or erasure that obliterates the original entry is acceptable.

The chain of custody, along with relevant testimony from individuals documented on the chain of custody documents, should provide a complete record of the *Sample* or *Aliquot* location.

fragment ions $C_3H_6O^+$ and $C_3H_8N^+$ both have the rounded mass 58 but the exact calculated mass of 58.04186 for $C_3H_6O^+$ and 58.06567 for $C_3H_8N^+$. Neither mass fragments can be separated by conventional (low resolution) mass spectrometry but only by using high resolution MS with a resolution of 2500. Thus in practical terms, in this example the instrument (HRMS) can be set to detect only the signal of the mass of 58.04186 for $C_3H_6O^+$, and all masses differing by more than 0.0024 masses, such as 58.06567 for $C_3H_8N^+$, will be discriminated. Based on this fundamental physical principle HRMS analysis of AAS steroids and their metabolites isolated from urine reduces the biological background and increases the signal-to-noise ratio, yielding a much higher selectivity in screening and confirmation.

24.5.4 Detection of endogenous anabolic androgenic steroids

24.5.4.1 Indirect detection methods

The misuse of testosterone by athletes is also tested by GC-MS analysis of urinary extracts. However, the method reveals only the presence of testosterone and its ratio to epitestosterone. The mass spectrometrical data alone indicate whether testosterone originates exogenously (doping) or whether it was produced endogenously. In 1983 Donike *et al.* developed a method to calculate urinary excreted testosterone by a ratio to 17-epitestosterone. Both isomeric steroid hormones are excreted mainly as glucuronides which are enzymatically hydrolyzed before GC-MS analysis. The urinary testosterone/epitestosterone ratio (T/E ratio) represents a relatively constant factor within an individual and alterations under physical exercise have not been noted. Exogenous application of testosterone results in an increase in the urinary concentration of testosterone glucuronide, whereas epitestosterone glucuronide is not influenced. Based on measurements of large reference groups Donike proposed a T/E ratio of 6:1 as a marker to handle a urine specimen suspicious for testosterone misuse. An increased T/E value ($T/E > 6$) is not immediately considered as a positive sample. Following the WADA rule the athlete has to be further investigated and it has to be determined that the increased value is not caused by physical or pathological conditions. In practice this requires several test samples of the athlete and evaluation of previous tests in order to establish the athlete's individual T/E reference values (subject-based reference values). The test sample is considered positive when the tested T/E ratio clearly exceeds the subject-based reference values ($> \text{mean} + 3 \text{ standard deviations}$) of the athlete. In addition to the T/E ratio the testosterone and epitestosterone concentrations as well as the concentrations of the main testosterone metabolites are assessed.

Doping with dihydrotestosterone (DHT) became public knowledge after the Asian Games in 1994 when seven athletes were tested positive for DHT misuse. The criteria for DHT doping are also based on statistical methods and population-based

fragment ions $C_3H_6O^+$ and $C_3H_8N^+$ both have the rounded mass 58 but the exact calculated mass of 58.04186 for $C_3H_6O^+$ and 58.06567 for $C_3H_8N^+$. Neither mass fragments can be separated by conventional (low resolution) mass spectrometry but only by using high resolution MS with a resolution of 2500. 24.5.4 Detection of endogenous anabolic androgenic steroids

24.5.4.1 Indirect detection methods

The misuse of testosterone by athletes is also tested by GC-MS analysis of urinary extracts. However, the method reveals only the presence of testosterone and its ratio to epitestosterone. The mass spectrometrical data alone indicate whether testosterone originates exogenously (doping) or whether it was produced endogenously. In 1983 Donike *et al.* developed a method to calculate urinary excreted testosterone by a ratio to 17-epitestosterone. Both isomeric steroid hormones are excreted mainly as glucuronides which are enzymatically hydrolyzed before GC-MS analysis. The urinary testosterone/epitestosterone ratio (T/E ratio) represents a relatively constant factor within an individual and alterations under physical exercise have not been noted. Exogenous application of testosterone results in an increase in the urinary concentration of testosterone glucuronide, whereas epitestosterone glucuronide is not influenced. Based on measurements of large reference groups Donike proposed a T/E ratio of 6:1 as a marker to handle a urine specimen suspicious for testosterone misuse. An increased T/E value ($T/E > 6$) is not immediately considered as a positive sample. Following the WADA rule the athlete has to be further investigated and it has to be determined that the increased value is not caused by physical or pathological conditions. In practice this requires several test samples of the athlete and evaluation of previous tests in order to establish the athlete's individual T/E reference values (subject-based reference values). The test sample is considered positive when the tested T/E ratio clearly exceeds the subject-based reference values ($> \text{mean} + 3 \text{ standard deviations}$) of the athlete. In addition to the T/E ratio the testosterone and epitestosterone concentrations as well as the concentrations of the main testosterone metabolites are assessed.

Doping with dihydrotestosterone (DHT) became public knowledge after the Asian Games in 1994 when seven athletes were tested positive for DHT misuse. The criteria for DHT doping are also based on statistical methods and population-based

Strasbourg, 31 July 2006

T-DO (2006) 29

Anti-Doping Convention (T-DO)

Meeting of the Advisory Group on Science (T-DO SCI) Strasbourg, 11 July 2006

Meeting report

1. Opening of the meeting

Michael PETROU (Cyprus), Chair of the Advisory Group, welcomed the participants (see List of participants in Appendix 1).

The representatives of WADA, as well as the Holy See, Luxembourg, the Netherlands and Switzerland, apologised for their absence.

2. Adoption of the agenda

The agenda was adopted as set out in Appendix 2.

3. Examination of the Draft List of Prohibited Substances for 2007 and recommendations to WADA

The Chair recalled that the present draft of the Prohibited List for 2007 had been circulated as document T-DO (2006) 22. This document includes the draft list as well as the list of modifications.

S1. Anabolic agents

Additional investigation in the event of a T/E ratio higher than four

Many delegates expressed their concern regarding the high cost of isotopic ratio analysis and stated that these analyses, and the additional investigation in cases of T/E ratio higher than four, constituted a significant additional workload, not only for the accredited laboratories, but also for the Anti-Doping Organisations.

Frans DELBEKE (Belgium – Flemish Community) explained that the World Association of Anti-Doping Scientists (WAADS) conducted a survey on the results of T/E analysis. 25 out of 33 accredited laboratories replied, representing 130,018 samples. 3265 of these samples produced an adverse analytical finding in 2005. Among these, 955 (29%) of the AAF had $4 < T/E < 6$. These samples had therefore to be confirmed either by IRMS or by reviewing the results of any previous test(s) or

conducting subsequent test(s). Only 3 of the 955 samples have been confirmed (2 by IRMS and 1 by follow-up study), but not all laboratories have IRMS and also the outcomes of follow-up or previous tests are not always known by the laboratories. However, only 2 of the 789 samples analysed by IRMS contained testosterone or its precursors.

With regard to cases with $T/E > 10$ which had been analysed with IRMS, the same survey provided the following results:

10 < T/E < 15: 11 confirmed, 14 not confirmed

15 < T/E < 20: 7 confirmed, 2 not confirmed

$T/E > 20$: 26 confirmed, 1 not confirmed

Many experts expressed the desire to be provided with more data and information on the rationale behind this threshold of 4:1. Moreover, given that reservations have been expressed on the validity of the IRMS method, scientific background for its use would also be appreciated.

The Group:

- *recommended that WADA maintains the threshold of (T/E) requesting additional investigations at 4 in 2007;*
- *expressed its concerns regarding the relevance of this value with regard to the necessary workload and the limited efficiency;*
- *urged WADA to gather and publish data:*
 - a) *on positive results identified for the different classes of T/E values, from both the laboratories and the NADOs;*
 - b) *on the current research on the detection method for exogenous testosterone;*
 - c) *on the cost of the decision to lower the threshold requesting additional investigation from 6 to 4;*
 - d) *on other information (intelligence of suspected misuse, deterrence effect of these analyses) which may be useful for deciding to keep this threshold on the list;*
- *declared its intention to review its position for the List 2008, in light of the data available;*
- *recommended that WADA continues to support research on analytical methods to detect exogenous testosterone;*
- *requested the secretariat of the Monitoring Group to distribute surveys or questionnaires among the States parties in order to provide the expected information before the discussion on the List 2008, in the event that WADA cannot commit itself to releasing it;*
- *drew the WADA secretariat's attention to the formatting of the title "Other Anabolic Agents, including, but not limited to:", which should be numbered with a "2."*

S3 Beta – 2 Agonists

The Group discussed the addition of procaterol to the list of exceptions that require an Abbreviated Therapeutic Use Exemption when administered only by inhalation, and found it logical.

The Group:

- *agreed with the addition of procaterol as proposed by WADA.*

S5 Diuretics and other masking agents

Cecilia RODRIGUEZ (Spain) stated that the problems related to the lack of references to the thresholds in the List, will increase with the footnote which makes reference to the thresholds and sub-threshold without mentioning them explicitly. The problem of threshold which are not enacted in official documents (but, for example, are in circular letters of recommendation as is the case of GCS) may open the door to appeals in countries where the List has to be published as a legal provision.

She also reported possible problems which may occur in the future with the entry into force of the Unesco Convention and the adoption of the List by Unesco and the Monitoring Group of the Council of Europe.

Stanislas FROSSARD (Secretariat of the CoE) took note of the issues, and recommended that these issues be discussed within the Advisory Group on Legal Issues, whose next meeting will take place on 31 August 2006. He also stated that the note mentioning the substances which are subjected to analytical thresholds (in other standards) will be added to the List submitted to the Monitoring Group.

The Group thoroughly discussed the alpha-reductase inhibitors (e.g. finasteride and dutasteride). Taking note of a study on finasteride by Geyer et al¹ (from the Institute of Biochemistry, German Sport University, Cologne, Germany), the Group decided after this discussion to keep the alpha-reductase inhibitors on the List. Considering the risk of error and accidental use without TUE, the Group decided to recommend their inclusion on the list of "Specified Substances".

The Group discussed the comment "*A Therapeutic Use Exemption (for diuretics) is not valid if an Athlete's urine contains a diuretic in association with threshold or sub-threshold levels of a Prohibited Substance(s)*" and considered the case of the detection of a diuretic in a sample with a level of 19-norandrosterone below the level of 2 ng/ml, which is natural. The Group however concluded that in such cases, the identification of exogenous origin of such substances could be detected and that a TUE for diuretic would be valid. The Group therefore decided not to recommend amendment of the note.

The Group:

- *recommended that WADA includes finasteride and dutasteride on the list of Specified Substances;*
- *requested the Advisory Group on Legal Issues to prepare a draft decision to clarify the relation between the list adopted by the Monitoring Group and the list adopted under the Unesco Convention, in order to prevent conflict.*

M1 Enhancement of oxygen transfer

The group discussed the wording of this category of methods.

The Group:

- *suggested replacing "use" by "administration" in point a.:*
 - a. *Blood doping, including the administration of autologous, homologous or heterologous blood or red blood cell products of any origin.*

¹ Geyer, H., Gorijs, I., Mareck, U., Thevis, M., Schanzer, W. (2006) Investigation about the effects and the detection of finasteride.

M2 Chemical and physical manipulation

The Group discussed the interpretation of the meaning of “legitimate acute medical treatment”.

Klaus MÜLLER (Germany) explained that as long as the infusion is decided on the basis of diagnosis, following the consideration of a patient’s situation, it will be considered as a “legitimate acute medical treatment”. However, in cases where a whole team systematically receives infusion after competition, it would not be seen as “legitimate acute medical treatment”.

Michael Petrou mentioned the case of discipline of athletes in sports with weight categories, where it sometimes occurs that athletes receive intravenous infusions in order to compensate for dehydration and/or nutritional deficiency caused by extreme weight loss practices, and raised the question whether such practices should not be prohibited more explicitly.

S6 Stimulants

Frans Delbeke commented on pseudoephedrine, and stated that since this substance has been removed from the List he has observed many cases of pseudoephedrine misuse. He mentioned the case of an athlete who admitted the ingestion of 320 mg in one day. Misuse of this stimulant appears to be quite common in cycling. A high level of cathin is often detected in the samples of these athletes, which suggests that the presence of cathin may be a metabolite of pseudoephedrine. He stated that he would suggest the reintroduction of pseudoephedrine on the List, with an analytical detection threshold at 25 µg/ml.

Luis HORTA (Portugal) and Günter GMEINER (Austria) also reported that they had taken note of numerous cases of misuse of pseudoephedrine, in certain sports. Luis Horta also referred to a recently published article by Hodges et al², which underlined the potential performance enhancing properties of pseudoephedrine.

Katia COLLOMP (France) suggested that WADA should promote comparative studies on the physiological effects of the different types of ephedrine, as well as their dosage.

Klaus Müller underlined that this issue highlights the more general problem of the implications of removing a substance from an open list. He underlined the sensitivity of the decision to remove a substance and the importance of providing very accurate results or studies before taking such a decision.

Hans COOMAN (Belgium), also proposed to put stimulants on the List of Prohibited Substances in and out-of-competition. The rationale for this is that athletes, in certain sport, use stimulants for training or recreational purposes.

The Group:

- ***recommended that WADA puts pseudoephedrine back on the Prohibited List, as a “Specified Substance” and urged WADA, if this is done, to draw the attention of the sport community on this change in the List.***
- ***recommended that WADA includes the stimulants in the List of Prohibited Substances at All Times (in and out-of-competition).***
- ***recommended that WADA removes the second part of the last paragraph on stimulants, in order to make the following sentence: “A stimulant not expressly mentioned as an example under this section should be considered as a specified substance”.***

² Hodges, K., Hancock, S., Currell, K., Hamilton, B., and Jeukendrup, A.E. (2006) Pseudoephedrine enhances performance in 1500-m runners, *Medicine & Science in Sports & Exercise*, 38 (2), pp 329-333.

S9 Cannabinoids

Classification of cannabinoids in "Substances Prohibited in Particular Sports"

Michael STOW (United Kingdom) expressed the position of his States which is in favour of removing cannabinoids from the List.

Hans Cooman expressed the position of Belgium which would be in favour of including cannabinoids in substances prohibited in particular sport.

Michael Petrou stated that cannabinoids are placed on the List based on their capacity to indirectly enhance performance for some athletes by reducing pre-competition anxiety and promoting euphoric mood state. And also that he considers the inclusion of Cannabinoids in the List of Substances Prohibited in Competition as justified.

The Group also mentioned the number of AAF related to cannabinoids, the slow extraction of the substance which makes it difficult to distinguish recent and less recent consumption, the political issues underlying the presence of cannabinoids on the list and agreed that the right place to challenge this old and much disputed issue would be the World Anti-Doping Conference in 2007 if the criteria for including Substances and Methods on the Prohibited List are changed.

The Group:

- *took note of the proposal of the delegates from Belgium to move the cannabinoids to the category P3 (substances prohibited in particular sports) and the position of the UK to remove them from the List.*

S9 Glucocorticosteroids

The delegates from Belgium criticised the current solution which had little sense, given that athletes who wish to misuse Glucocorticosteroids can allege dermatological problems or use a TUE. The threshold of 30 ng/ml also appeared to be much too high.

Representatives of France and Portugal recognised that the present situation is unsatisfactory.

Cecilia Rodriguez complained about the lack of description of the substances covered by this class, as well as the lack of provision defining the detection threshold (except a recommendation letter to the laboratories).

The Group:

- *asked WADA to keep the Glucocorticosteroids on the List;*
- *recommended that WADA considers:*
 - *including an open list of substances as examples;*
 - *lowering the reporting level;*
- *expressed its concerns regarding the present misuse of Glucocorticosteroids.*

P1 Alcohol

The Group:

- *recommended that WADA states that the threshold values mentioned are related to blood analysis.*

Specified Substances

The Group:

- *recommended that WADA completes the line on Beta-2 agonists with "except clenbuterol and salbutamol above 1000 ng/ml".*
- *recommended the inclusion of Pseudoephedrine*
- *recommended the inclusion of finasteride and dutasteride*

4. Artificially-induced hypoxic conditions

Michael Petrou explained that this item was placed on the revised version of the Agenda after it was received from WADA consultation from its Ethical Issues Review Panel. In order to launch the discussion with background information on previously adopted decisions, Stanislas Frossard presented the previous declaration adopted by the Monitoring Group on this issue.

*Declaration on the use of altitude rooms/hyperbaric chambers
adopted by the Monitoring Group at its 11th Meeting on 30 – 31 March 2000 in Strasbourg:*

As forbidding these techniques is not the best solution, the Group suggests warning those concerned of the risks of these processes:

High-altitude training is permitted for athletes, and it cannot be banned for specific reasons: some nations/athletes are normally located at high altitudes. Artificial environments mimicking the main consequence of high altitude (lowering of the partial pressure of oxygen, i.e. the percentage of oxygen in the inspired air) could theoretically be banned, because they are unnatural, and can be controlled.

Contrary to natural high altitude, artificial means (hypoxic chambers) are not limited to conditions corresponding to several thousand meters above sea level: their pressure or oxygen content can theoretically be expanded to unnatural, dangerous or even lethal measures.

On the other hand, the real benefit in performance enhancement will certainly depend on further conditions: while enhanced performances have been observed under specific circumstances, they may lack under other ones.

Different technical concepts play an additional role: hypobaric chambers similar to high geographical altitude provide low air pressure and lower oxygen content per inhaled volume simultaneously, whereas other chambers lower only the oxygen content (lower percentage than the normal 20%). The physiological consequences or risks of those different conditions, as well as the influence on performance, may differ.

In general, these considerations must assume technical perfection. Serious risks could occur, if the predetermined, physiologically justified parameters could not be technically guaranteed.

But the possibility of obtaining similar effects by natural (although more expensive and more time-consuming) means, should be discouraged for at least unreasonably extended use, but these methods should not be prohibited for the meantime.

Stanislas Frossard also summarised the relevant discussion of the Advisory Group held in April 2005:

Many participants to the meeting expressed the need for safety standards for the commercialised hypoxic equipments, as well as the need for adequate education, so that those "training methods" do not pose a safety hazard. Some ethical concerns were also discussed (health risks, and in particular mental health risks, equity between countries, risk of abuse or misuse, medical supervision ...).

Following the presentations and extensive discussions, the Advisory Group on Science did not recommend including artificial altitude training methods as a prohibited doping method. As such methods are artificial, they may raise some ethical issues. Such methods, designed to lower oxygen content in blood, mimic natural high altitude conditions. If such methods should be used, it should only be under controlled parameters (altitude, duration, exposure) and under medical supervision.

The Group recognised that these methods have a performance enhancing potential and underlined some health risks (i.e. inappropriate use and quality/safety of equipment). The Group expressed ethical concerns related to the fact that the method is artificial.

The WADA Ethical Committee, in its recently released new contribution on the analysis of the compliance of these methods with the spirit of sport, concluded that hypoxic chambers may be seen as not complying with the spirit of sport, as defined in the introduction of the Code.

Luis Horta expressed his doubts with regard to the criteria of passivity of the athlete which has been developed by the ethical committee, as this would also challenge methods like electro stimulation, air conditioning, baths, etc.

Many experts took the floor to raise concerns about the inclusion of these methods on the List. At present, there are 3 criteria for allowing the inclusion of prohibited substances and methods on the List, but do not make this inclusion compulsory.

Warning letters from groups of scientists, although they do not represent the scientific community in general, should also be taken into consideration.

Richard L. HILDERBRAND (USA) reported that many of the physicians attending the recent American College of Sport Medicine meeting made comments against WADA controlling hypoxic chambers.

The Group, however, underlined that being against prohibition should not be interpreted as promoting this kind of method.

The Group:

- *took note that there is, at present, no support to prohibit the hypoxic chambers through their inclusion on the prohibited list;*
- *considered that, at present, all arguments are not in favour of prohibition;*
- *expressed concerns about the negative consequences of the use of the methods and invited WADA, the sport organisations and the public authorities to express warnings against the risks of hypoxic chambers and to reconsider the issue at a later date, where appropriate;*
- *asked the secretariat to invite the Bioethics Committee to give an additional independent opinion from experts on the ethical criteria (compliance of hypoxic chambers with the spirit of sport as defined in the Code).*

5. Other matters

The secretariat informed delegates that the report of the previous meeting had been released and apologised that its adoption had not been put on the agenda of the Advisory Group, as it was unclear at the time of the adoption of the agenda whether the report would be available in both languages. This report will be submitted directly to the Monitoring Group in November. However, comments from participants can be sent to the Secretariat and will be taken into consideration with the approval of the Chair of the Group.

6. Next meeting

The next meeting of the Group will take place in spring 2007. The exact date may have to be co-ordinated with the other Advisory Groups and will therefore be released at the Monitoring Group meeting.

7. Close of the meeting

The Chair thanked all participants and closed the meeting.

GCMS: How Does It Work?

How does the GCMS work?

The GCMS instrument is made up of two parts. The gas chromatography (GC) portion separates the chemical mixture into pulses of pure chemicals and the mass spectrometer (MS) identifies and quantifies the chemicals.

The GC separates chemicals based on their volatility, or ease with which they evaporate into a gas. It is similar to a running race where a group of people begin at the starting line, but as the race proceeds, the runners separate based on their speed. The chemicals in the mixture separate based on their volatility. In general, small molecules travel more quickly than larger molecules.

The MS is used to identify chemicals based on their structure. Let's say after completing a puzzle, you accidentally drop it on the floor. Some parts of the puzzle remain attached together and some individual pieces break off completely. By looking at these various pieces, you are still able to get an idea of what the original puzzle looked like. This is very similar to the way that the mass spectrometer works.

1. Gas chromatography (GC)

- Injection port** – One microliter (1 μL , or 0.000001 L) of solvent containing the mixture of molecules is injected into the GC and the sample is carried by inert (non-reactive) gas through the instrument, usually helium. The inject port is heated to 300° C to cause the chemicals to become gases.
- Oven** – The outer part of the GC is a very specialized **oven**. The column is heated to move the molecules through the column. Typical oven temperatures range from 40° C to 320° C.
- Column** – Inside the oven is the **column** which is a 30 meter thin tube with a special polymer coating on the inside. Chemical mixtures are separated based on their volatility and are carried through the column by helium. Chemicals with high volatility travel through the column more quickly than chemicals with low volatility.

2. Mass Spectrometer (MS)

- A. **Ion Source:** After passing through the GC, the chemical pulses continue to the MS. The molecules are blasted with electrons, which cause them to break into pieces and turn into positively charged particles called **ions**. This is important because the particles must be charged to pass through the filter.
- B. **Filter**– As the ions continue through the MS, they travel through an electromagnetic field that filters the ions based on mass. The scientist using the instrument chooses what range of masses should be allowed through the filter. The filter continuously scans through the range of masses as the stream of ions come from the ion source.
- C. **Detector** – A detector counts the number of ions with a specific mass. This information is sent to a computer and a **mass spectrum** is created. The mass spectrum is a graph of the number of ions with different masses that traveled through the filter.

3. Computer

- A. The data from the mass spectrometer is sent to a computer and plotted on a graph called a **mass spectrum**.

Anabolic Steroids

CYNTHIA M. KUHN

*Department of Pharmacology and Cancer Biology, Duke University Medical Center,
Durham, North Carolina 27710*

ABSTRACT

The term “anabolic steroids” refers to testosterone derivatives that are used either clinically or by athletes for their anabolic properties. However, scientists have questioned the anabolic effects of testosterone and its derivatives in normal men for decades. Most scientists concluded that anabolic steroids do not increase muscle size or strength in people with normal gonadal function and have discounted positive results as unduly influenced by positive expectations of athletes, inferior experimental design, or poor data analysis. There has been a tremendous disconnect between the conviction of athletes that these drugs are effective and the conviction of scientists that they aren't. In part, this disconnect results from the completely different dose regimens used by scientists to document the correction of deficiency states and by athletes striving to optimize athletic performance. Recently, careful scientific study of suprapharmacologic doses in clinical settings – including aging, human immunodeficiency virus, and other disease states – supports the efficacy of these regimens. However, the mechanism by which these doses act remains unclear.

“Anabolism” is defined as any state in which nitrogen is differentially retained in lean body mass, either through stimulation of protein synthesis and/or decreased breakdown of protein anywhere in the body. Testosterone, the main gonadal steroid in males, has marked anabolic effects in addition to its effects on reproduction that are easily observed in developing boys and when hypogonadal men receive testosterone as replacement therapy. However, its efficacy in normal men, as during its use in athletes or in clinical situations in which men are eugonadal, has been debated. A growing literature suggests that use of suprapharmacologic doses can, indeed, be anabolic in certain situations; however, the clear identification of these situations and the mechanism by which anabolic effects occur are unclear. Furthermore, the pharmacology of “anabolism” is in its infancy: no drugs currently available are “purely” anabolic but all possess androgenic properties as well. The present review briefly recapitulates the historic literature about the androgenic/anabolic steroids and describes literature supporting the anabolic activity of these drugs in normal people, focusing on the use of suprapharmacologic doses by athletes and clinicians to achieve anabolic effects in normal humans. We will present the emerging literature that is beginning to explore more specific mechanisms that might mediate the effects of suprapharmacologic regimens. The terms anabolic/androgenic steroids will be used throughout to reflect the combined actions of all drugs that are currently available.

I. Use of Suprapharmacologic Doses of Anabolic/Androgenic Steroids (AAS)

People have been taking testosterone to restore “vitality” since the efficacy of some hormonal component of the testes was first described by Brown-Sequard

in 1889. He reported the reversal of his own aging by self-injection of a testicular extract, thereby stimulated a flurry of experimentation into the putative anti-aging effects of testicular hormones long before the identity of testosterone was confirmed. The first use to improve athletic performance occurred shortly thereafter, in 1896. A contemporary of Brown-Sequard self-administered testicular extract, then measured his finger strength. Athletes have been using purified testosterone since it was first available (see a review of this early history in Yesalis *et al.*, 2000). The modern use of anabolic steroids in athletic competition dates from the Olympic competitions during the Cold War era. Russian athletes were putatively the first to use anabolic steroids to improve athletic performance in international competitions. Although the International Olympic Committee banned use of anabolic agents in 1964, the practice spread and probably reached its pinnacle in the athletic programs in Germany during the 1970s (Yesalis *et al.*, 2000).

Medical use of testicular extract began in the late 1800s. Clinical use of supraphysiological doses of AAS in eugonadal patients for anabolic benefit started in the 1940s. High-dose AAS regimens have been used to promote muscle deposition after burns, surgery, radiation therapy, and aging-related sarcopenia (muscle wasting). Recent uses include treating wasting in human immunodeficiency virus (HIV) and contraception (Bhasin *et al.*, 1996,1997; Amory and Bremner, 2000).

II. Anabolic Steroids

All steroids that are anabolic are derivatives of testosterone and are androgenic as well as anabolic, as they stimulate growth and function of male reproductive tract. Individual drugs vary in their balance of anabolic:androgen activity but none of the currently available drugs are purely anabolic. All the anabolic steroids currently used are derivatives of testosterone or are structural modifications of testosterone that influence its pharmacokinetics, bioavailability, or balance of androgenic to anabolic activity. These include testosterone itself, all of the derivatives that are used clinically, as well as numerous plant products that at least claim to possess anabolic actions.

The testosterone derivatives available in the United States comprise several groups: 1) endogenously produced androgens or their precursors, including testosterone and androstenedione; 2) synthetic derivatives of testosterone with altered metabolic or receptor-binding characteristics; and 3) various uncharacterized plant or animal materials. Testosterone actions represent the combination of several activities. First, it binds to the androgen receptor to exert its androgenic activity. Second, it is 5 α reduced in some target tissues (including the male urogenital tract, skin, liver, and sebaceous glands) to dihydrotestosterone (DHT), which also acts on the androgen receptor. Finally, it can be aromatized to

estradiol and exert estrogenic activities. The latter two actions are highly undesirable in anabolic drugs, 5α reduction because it decreases the ratio of anabolic:androgenic activity and aromatization because of the feminizing side effects.

Structural and pharmacokinetic properties have been reviewed extensively (Wilson, 1988,1996) and are abstracted briefly here (see Figures 1 and 2).

1. Testosterone as an injectable form, a transdermal patch, skin cream, and a micronized oral preparation

2. $17\text{-}\beta$ esters of testosterone: testosterone cypionate, propionate, enanthate, and undecanoate. Esterification at this site renders the steroid more fat soluble and delays absorption into the circulation. All but the undecanoate must be injected. Nandrolone $17\text{-}\beta$ esters also exist.

3. $17\text{-}\alpha$ derivatives (methyltestosterone, methandrostenolone, norethandrolone, fluoxymesterone, danazol, oxandrolone, stanozol). These derivatives resist metabolism in the liver, so are orally active. This modification is associated with significant hepatic toxicities.

4. Modifications of the A, B, or C rings (mesterolone, nortestosterone, methenolone, fluoxymesterone, methandrostenolone, nandrolone, danazol, nandrolone, stanozol). These modifications achieve a number of goals, including a) slow metabolism; b) enhanced affinity for the androgen receptor (19-nortestosterone); c) resistance to aromatization to estradiol (fluoxymesterone, 19-nortestosterone); and d) decreased binding of metabolites to androgen receptor (5α -reduced metabolites of 19-nortestosterone, 7α -19-nortestosterone).

Structure:activity modifications that limit either conversion to DHT and/or to estradiol partially target specific testosterone derivatives to specific activities. Agents such as fluoxymesterone and 19-nortestosterone (nandrolone) that resist aromatization lack the feminizing side effects of testosterone. 19-nortestosterone possesses another characteristic that increases its anabolic activity because its

FIG. 1. Model testosterone structure. [Reprinted with permission from Wilson JD 1998 Androgen abuse by athletes. Endocr Rev 9:181-191. Copyright The Endocrine Society.]

FIG. 2. Structures of several anabolic steroids. [Reprinted with permission from Wilson JD 1998 Androgen abuse by athletes. Endocr Rev 9:181-191. Copyright The Endocrine Society.]

5 α -reduced metabolite has poor affinity for the androgen receptor. Similarly, alpha-methyl-19-nortestosterone is not a substrate for 5 α reductase (Sundaram *et al.*, 1995).

Finally, a number of "natural products" that are purported to exhibit anabolic qualities are marketed freely in the United States due to the exemption of "natural products" from U.S. Food and Drug Administration regulation. Most of these are steroid precursors. Androstenedione and norandrostenedione are two widely marketed precursors. Marketers claim that they are converted into testosterone and nortestosterone (nandrolone). While a small percentage is, indeed, converted, the total amount produced is likely far below that which would have any anabolic activity in a eugonadal male. Finally, there are undefined mixtures with catchy names like "Horny Goat Weed" and "Testicular Extract" that are derived from both plant and animal materials and contain absolutely unknown ingredients.

All of the drugs listed above possess both anabolic and androgenic activities; none are absolutely selective. However, this ratio varies across a broad range. Table I shows the approximate anabolic:androgenic ratio of a number of clinically used AAS. The range is fairly narrow by clinical standards. All anabolic steroids are virilizing if administered for long enough at high enough doses.

These values are based on data collected in the 1950s and 1960s from bioassays of varying degrees of specificity and accuracy (see excellent historical review in Kochakian, 1976). Typically, the ability of a test drug to stimulate growth of a skeletal muscle and a reproductive target (prostate gland) was assessed. Two classic methods for establishing anabolic efficacy were the stimulation of growth of the levator ani muscle in the castrated rodent and stimulation of whole-body nitrogen retention in a castrated animal. Neither of these are ideal measures. The levator ani muscle may actually reflect androgenic efficacy of AAS because it can be viewed as part of the reproductive system. Its use as a bioassay for "anabolic" activity has been questioned. While the

TABLE I
Anabolic:Androgenic Ratio for Selected Anabolic Drugs

| Anabolic/androgenic steroid | Anabolic:androgenic ratio |
|----------------------------------|---------------------------|
| Testosterone, methyltestosterone | 1 |
| Methandrostenolone | 2-5 |
| Oxymetholone | 9 |
| Oxandrolone | 10 |
| Nandrolone | 10 |
| Stanozol | 30 |

nitrogen-retention assay is better, it provides an extremely indirect measure of muscle deposition.

There has been virtually no investigation of the relative anabolic and androgenic properties of AAS since the mid-1970s and none using more modern tools to assess androgen receptor activity. One major goal of this chapter is to summarize recent developments in the molecular pharmacology of androgen receptors that are opening this area up for pharmaceutical development.

III. Androstenedione

In the summer of 1998, baseball player Mark McGwire revealed that he took regular androstenedione supplements during the season that he set a new home run record. The first scientific study of the anabolic efficacy of androstenedione appeared shortly thereafter (King *et al.*, 1999). This study showed that giving modest doses to untrained men who were started on an exercise program increased testosterone only transiently at the higher (i.e., 300-mg) dose but did not improve strength. However, it did increase plasma estradiol levels, a finding that was confirmed in a later study (Leder *et al.*, 2000). That is, this study recapitulated the large number of negative studies in the literature that documented that such combinations of training and AAS were no more effective than training alone. This study has been replicated in older men using a similar design (Broeder *et al.*, 2000). In this case, users took doses recommended by supplement manufacturers while they were engaged in resistance training. The results of both studies were similar: neither younger nor older subjects who received androstenedione showed greater increases in strength than those who received placebo, although circulating lipid profiles changed in the direction of greater cardiovascular risk (low-density to high-density lipoprotein/apolipoprotein A/apolipoprotein B) ratio. Since, at most, 10–15% of a dose is converted to testosterone, it is unlikely that regimens used by athletes will prove anabolic but the research has not been conducted. No published studies report effective anabolic activity of suprapharmacologic doses of androstenedione.

IV. Do Anabolic Steroids Increase Muscle Size and/or Strength in Eugonadal Men?

The anabolic effects of restoring normal physiologic levels of testosterone in hypogonadal men are uncontested. The rise in testosterone during puberty contributes to the increase in linear growth as well as muscle deposition at that time. Increased muscle deposition clearly results when hypogonadal men receive testosterone treatment (Kopera, 1985; Wilson, 1996; Bross *et al.*, 1999). AAS also can be anabolic in men who are hypogonadal as a result of disease such as HIV or after burns (Bhasin *et al.*, 1996, 1999).

The anabolic effects of testosterone derivatives in women athletes are similarly explicable, as circulating testosterone levels of women are typically about 10% of those observed in men (Wilson, 1996). Therefore, raising female testosterone levels to those comparable to males provides supraphysiologic levels. Although there are very few published studies of muscle size and strength after AAS use in women, one report found elevations up to 30-fold of normal levels in women who were self-administering AAS (Malarkey *et al.*, 1991). There are virtually no controlled studies of AAS effects on women for obvious ethical reasons but dramatic evidence of these effects derives from the recently released results of the East German sports program of the 1970s and 1980s (Franke and Berendonk, 1997). Figure 3 shows shotput performance of a female German athlete, with the bars below indicating the periods of AAS administration. Unfortunately, women receiving AAS inevitably experience the androgenization associated with these drugs.

The benefit of anabolic steroid use for eugonadal men is far more controversial.

FIG. 3. Shot-put performance of woman athlete from East Germany. [Redrawn from Franke WW, Berendonk B 1997 Hormonal doping and androgenization of athletes: a secret program of the German Democratic Republic government. Clin Chem 43:1262-1279.]

For decades, scientists argued that anabolic steroids do not increase muscle mass or strength in normal men. This was based first on clinical experience that suggested that the nitrogen-retaining effects of testosterone treatment to normal men were modest and transient (Wilson, 1996). The controversy between those who state that anabolic steroids do not increase muscle mass or strength and those who believe in their effectiveness derives in part from which body of research is cited. Many critics properly cite many negative studies in which addition of testosterone or another AAS to a training regimen failed to improve performance (see reviews in Wilson, 1988; Elashoff *et al.*, 1991; O'Connor and Cicero, 1993; Friedl, 2000). They also critique the poor study design in studies conducted in athletes, including lack of placebo control, nonblinded study conditions, reliance on case studies or small study populations, lack of standardization of dose and training regimen, and the impact that expectation of benefit had on results.

These differences in study design might well play an important part in the different findings. First, nonfit people who are started on a training regimen generally experience such substantial benefit from the training regimen alone that it is difficult to show an additive benefit of AAS. The use of physiologic doses of AAS contributed to this problem. Little benefit of increasing testosterone within the physiologic range has been demonstrated in such studies. Furthermore, the dependent measure chosen to assess muscle strength is critical. Testosterone increases upper body mass differentially, so performance in tasks like weightlifting should improve more than lower-body tasks or tasks in which aerobic capacity rather than strength are assessed. As expected, the task in which increases have been reported most reliably are in the bench press (Friedl, 2000). Finally, the degree of improvement expected in such studies is generally small. Changes in performance of 1–5% are rarely statistically or clinically significant but they represent the margin of victory for elite athletes. Therefore, scientists, clinicians, and athletes all might interpret data from the same study quite differently.

Controversies about anabolic effects of AAS in animals have been similar but less intense. The same factors have entered into the outcome: gender of animals, conducting the study in trained vs. sedentary animals, dose regimen, and duration of exposure. AAS do effectively increase muscle size, protein content, and contractility in both male and female rats (Exner *et al.*, 1973; Menschikowski *et al.*, 1988; Lewis *et al.*, 1999), although negative findings have been reported (Bates *et al.*, 1987). Efficacy of AAS in trained animals has been established (Lubek *et al.*, 1984; Elashoff *et al.*, 1991; Lewis *et al.*, 1999), although different muscle beds respond differentially and slow twitch muscles improve more than fast twitch (Sachs and Leipheimer, 1988; Lewis *et al.*, 1999; Joumaa and Leoty, 2001).

V. Challenging the Conventional Wisdom: AAS Can Increase Muscle Size and Strength in Normal Men

Studies providing suprapharmacologic doses, using maximally trained athletes and testing performance in tasks like weightlifting, are mainly likely to show an effect of AAS. A recent study showing clear, statistically significant increases in muscle mass and strength after AAS administration in a proper placebo-controlled, blinded study may help put these controversies to rest. This complemented previous studies from the same laboratory demonstrating benefit in hypogonadal, HIV-infected men using the same strategy (Bhasin *et al.*, 1996,1999,2001; Strawford *et al.*, 1999).

Biochemical and anatomical studies show that AAS do significantly influence muscle morphology and biochemistry in humans. Body weight reliably increases after AAS use and part of the increase is in lean body mass, although part also reflects retention of water (see recent review in Friedl, 2000). Muscle biopsies in weightlifters reported that both the number of muscle fibers and average fiber size in the trapezius muscle were greater in AAS users than nonusers (Doumit *et al.*, 1996; Kadi *et al.*, 1999a). Controlled studies show that both the number of muscle fibers and the size of individual fibers increase with AAS treatment in animal models (Joubert and Tobin, 1989). Both of these processes depend upon activation of satellite cells within the muscle. Satellite cells contain androgen receptors (Doumit *et al.*, 1996). AAS action within these cells to stimulate proliferation may represent an important mechanism of AAS action. The specific genes that are regulated by androgens in the muscle are unknown. Muscle biopsies in AAS-using powerlifters, in comparison to drug-free powerlifters, showed increased expression of embryonic forms of myosin and the Leu-19 antigen that is expressed in developing myotubes and newly formed myonuclei. This finding supports the hypothesis that AAS trigger both hypertrophy and hyperplasia but does not elucidate the specific genes that are activated (Kadi *et al.*, 1999a,b,2000).

Increases in strength can also result not from hypertrophy or hyperplasia but from increased expression of specific elements of the contractile apparatus. Again, this has been little studied. However, a recent study (Joumaa and Leoty, 2001) began to address this phenomenon by evaluating potassium and caffeine-induced contractures. Both the magnitude of potassium-induced contractures and the rate of recovery were greater in slow-twitch muscles of animals that received training and nandrolone. The authors speculated that these results suggested changes in both the activation mechanism and recovery mechanisms that sequester calcium in the sarcoplasmic reticulum. Enhanced caffeine contractures could reflect enhanced calcium release from the sarcoplasmic reticulum or changes in the calcium sensitivity of the contractile proteins.

VI. Mechanism of Anabolic Effect in Eugonadal Men

A. ROLE OF SUPRAPHARMACOLOGIC DOSES

The mechanism by which AAS increase muscle size and strength is surprisingly confusing. Androgen receptors clearly mediate the increase in muscle size and protein synthesis in hypogonadal men and during puberty. In these situations, androgen increases net nitrogen balance, increases lean body mass, and increases the rate of muscle protein synthesis (see review by Wilson, 1996). However, it often is asserted that comparable effects are not observed in men with normal gonadal function because androgen receptors are saturated at physiologic levels of testosterone. If androgen effects are mediated by androgen receptors, which are saturated at physiologic levels of testosterone, then no additional benefit should result from providing more androgen.

Steroid regimens favored by athletes differ markedly from those used clinically to provide replacement for hypogonadal men. Athletes use suprapharmacologic doses and typically "stack" multiple drugs at total androgen doses that range from 10–100-fold above normal levels (Wilson, 1988). Typically, they take androgens in cycles of weeks, with drug holidays interspersed of weeks or months. Many athletes use "stacking" regimens that involve taking multiple agents simultaneously, and/or a pyramiding dose regimen in which doses are started low, increased, then tapered back down.

A small but expanding literature suggests that suprapharmacologic doses are effective in eugonadal men. The active hormone is probably testosterone, since 5α reductase is not present in muscle (Wilson and Gloyna, 1970). Two older studies (Griggs *et al.*, 1989; Forbes *et al.*, 1992) have been supplemented by several recent findings demonstrating increased lean body mass, muscle protein synthesis, and/or positive nitrogen balance in normal men after high doses of AAS (Bhasin *et al.*, 1996; Ferrando *et al.*, 1998; Sheffield-Moore *et al.*, 1999; Strawford *et al.*, 1999; see also review in Sheffield-Moore, 2000). The most important recent finding is the dose-response study showing that androgenic effects of testosterone saturate at fairly low doses, in contrast to measurable anabolic effects, which require considerably higher doses (Bhasin *et al.*, 1999).

B. ANDROGEN RECEPTOR IN AAS: EFFECTS ON EUGONADAL MEN

The finding that muscle hypertrophy associated with exercise is blocked by androgen antagonists (Inoue *et al.*, 1994) supports a primary role for androgen receptors in exercise-induced muscle hypertrophy. One androgen receptor has been cloned (see review by Lamb *et al.*, 2001) and while its expression varies quantitatively in muscle and reproductive tissues (Sar *et al.*, 1990; Kimura *et al.*, 1993), it is likely that this receptor mediates AAS effects in the muscle. The one study comparing the binding of a range of AAS to skeletal muscle and prostate

reported, as expected, that little tissue specificity in binding affinity was observed across a broad range in binding affinities (Saartok *et al.*, 1984). Androgen receptors are present in skeletal muscle of every mammalian species (Sar *et al.*, 1990; Takeda *et al.*, 1990). Levels of expression differ from muscle bed to muscle bed in a manner consistent with reported AAS effects on muscle strength in different tasks. For example, human muscle beds differ from each other, with expression higher in the muscles of the neck and chest girdle, in comparison to the limbs (Kadi *et al.*, 2000).

Recent studies in multiple species show that androgen receptor can be upregulated by exposure to AAS (Bricout *et al.*, 1994; Doumit *et al.*, 1996; Sheffield-Moore *et al.*, 1999; Kadi *et al.*, 2000). The induction reported in humans (Sheffield-Moore *et al.*, 1999) suggests that suprapharmacologic concentrations might be effective because they increase the population of androgen receptors upon which they can act. These findings suggest at least one potential mechanism by which high doses could elicit different effects than physiologic doses.

In summary, two aspects of androgen receptor expression can influence the magnitude of anabolic effects: variations from muscle bed to muscle bed in androgen receptor expression and induction of androgen receptor expression after treatment with AAS. These are shown schematically in Figure 4.

Recent insights into the organization of the steroid hormone receptor:DNA complex suggest an alternative explanation for the varying anabolic:androgenic ratio of AAS. Steroid hormone receptors form a "tripartite" complex between ligand, receptor, and effector that can have varying actions (Katzenellenbogen *et al.*, 1996). When steroid hormones or their analogues bind to their receptor, they form a complex that binds to DNA. However, the receptor:DNA complex also binds a group of adaptor proteins that influence the transcriptional consequences of receptor binding to DNA. These proteins function as coactivators or co-repressors to enhance or prevent activation of transcription by the receptor (Torchia *et al.*, 1998). Each drug that binds steroid hormone receptor induces a particular "shape" in the drug:receptor complex that permits a unique pattern of adapter protein association. The adapter proteins that associate influence the consequence of drug:receptor binding on transcription (Darimont *et al.*, 1998). Selectivity can derive from the drug, the receptor, or the pattern of adaptor protein expression. This model has been exploited successfully in the development of tissue-selective estrogenic compounds. Different estrogenic compounds have specific actions, depending upon the coactivator and/or co-repressor environment (see McDonnell *et al.*, this volume).

A recent commentary (Negro-Vilar, 1999) suggests that a similar approach could be considered for androgens. Up to six different coactivators that are relatively specific for the androgen receptor have been described in the literature (Yeh and Chang, 1996; Fujimoto *et al.*, 1999; Kang *et al.*, 1999; Muller *et al.*,

FIG. 4. Model cell containing nucleus with few (top) or more (bottom) androgen receptors. Top represents head and neck muscle relative to leg or normal individual compared to AAS-treated individual.

2000). Although tissue distribution is incompletely described, all are expressed in testis and prostate with widely varying levels of expression in other androgen target tissues. One, FHL2, is expressed highly in heart, slightly in prostate, but not elsewhere (Muller *et al.*, 2000). This coactivator is the first described that is expressed more highly in a nonreproductive tissue than in reproductive tissues. Its existence suggests that tissue-specific distribution of coactivators could theoretically contribute to the ability of different AAS agonists to vary in their ratio of actions in different tissues due to the different tissue distribution of coactivators or co-repressors. Information from a different source supports the possibility that different agonists do induce different conformations of the drug:receptor complex. An NH₂-terminal and carboxyl-terminal interaction of the androgen receptor occurs in the presence of agonist binding (Langley *et al.*, 1995). In a co-transfection system, this interaction parallels agonist activity to a degree but weak agonists like medroxyprogesterone possess agonist activity in

the absence of this interaction (Kemppainen *et al.*, 1999). However, the study of androgen receptor interactions of this type is in its infancy. It suggests that nonselective steroids like testosterone might occupy the androgen receptor in a way that produces a receptor conformation that permits binding of both general and tissue-selective co-activators (Figure 5). Model drugs with selective actions would result in a ligand:receptor conformation that permitted association only of one set of tissue-selective ligands (Figure 6).

C. ANTICATABOLIC EFFECTS OF ANDROGENS

There is also evidence to support a role for anticatabolic mechanisms in the anabolic effects of suprapharmacologic AAS regimens. A recent case report of two patients with a point mutation in the androgen receptor that rendered it inactive showed that a suprapharmacologic steroid regimen was anabolic in both individuals (Tincello *et al.*, 1997). Evidence from animal models also supports this possibility. These begin with binding studies that show that androgens can bind, albeit at low affinity, to glucocorticoid receptors (Danheive and Rousseau, 1986,1988). Such low-affinity binding would not be effective, unless extremely

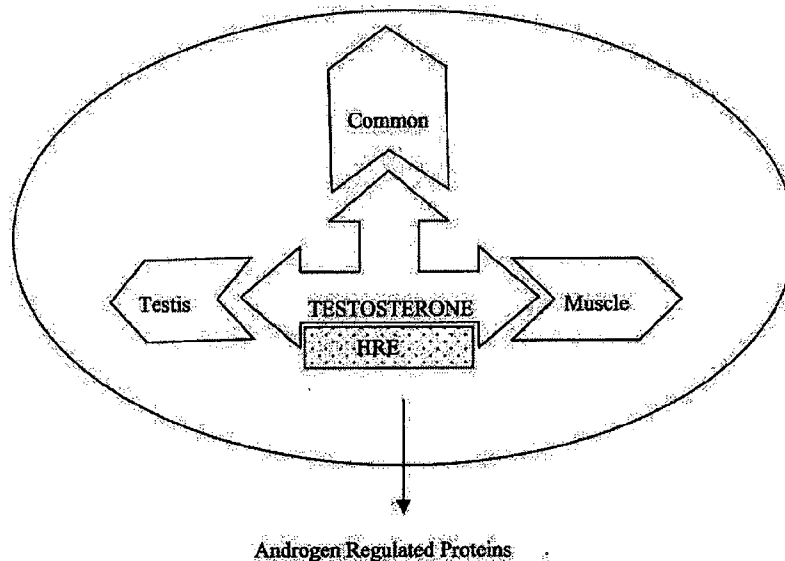

FIG. 5. Model of testosterone activation of androgen receptor (showing just one of the two ligand:receptor dimers that bind to DNA and activate transcription). HRE = hormone response element.

FIG. 6. Hypothetical ligand-occupied androgen receptor conformations that would allow an agonist to recruit coactivators in a tissue-specific way.

high doses of AAS were present. More directly, testosterone can block glucocorticoid-mediated induction of tyrosine amino transferase in liver just like the glucocorticoid antagonist RU486 (Danhaive and Rousseau 1986,1988). However, androgen blockade of glucocorticoid-induced muscle wasting is not observed consistently (see review by Hickson *et al.*, 1990). Furthermore, in healthy young men as well as in burn patients, the anabolic steroid oxandrolone has been shown to increase net protein synthesis without slowing protein degradation (Sheffield-Moore *et al.*, 1999; Hart *et al.*, 2001). Therefore, the specific contribution of glucocorticoid antagonism in AAS-induced anabolic effects has not been demonstrated unequivocally.

D. COMPLEMENTARY EFFECTS ON GROWTH HORMONE SECRETION AND INSULIN-LIKE GROWTH FACTOR-1 PRODUCTION

The growth hormone (GH)-insulin-like growth factor-1 (IGF-1) axis is thought to contribute to the anabolic effects of testosterone, both through androgen-induced stimulation of GH secretion and direct stimulation of hepatic production of IGF-1 (Rosenfeld *et al.*, 1994; Veldhuis and Iranmanesh, 1996). IGF-1 can stimulate skeletal muscle formation (Florini *et al.*, 1991). Increases in IGF mRNA have been reported in rats following nandrolone administration and increases in both IGF mRNA and circulating IGF-1 occur in men after testosterone treatment (Urban *et al.*, 1995; Gayan-Ramirez *et al.*, 2000) and decreases in mRNA occur when gonadal function is suppressed (Mauras *et al.*, 1998). However, none of these studies measured IGF-1 directly or established the relationship between IGF-1 and anabolic effects of the drugs.

E. COMPLEMENTARY EFFECTS OF TRAINING AND AAS

One of the challenges involved in understanding the effects of AAS in normal athletes is that many of the endpoints (e.g., muscle size, strength) are enhanced by training. Most studies of AAS action involve administration of AAS to sedentary animals, which presents a clear picture of what isolated AAS administration can achieve. Furthermore, comparing the benefits of beginning an exercise regimen and/or AAS in an unfit person provides a model for potential treatment of patient populations such as patients with HIV or the elderly. It does not replicate the environment in which AAS are most often used, which is in a highly trained athlete who is adding AAS to a rigorous exercise regimen. Clearly, exercise increases muscle mass on its own. The prospective, placebo-controlled testosterone trial in eugonadal men by Bhasin and colleagues (1996) that compared placebo, testosterone, exercise, or exercise plus testosterone showed clearly that effects of testosterone and resistance exercise were additive. Another recent study suggests a possible mechanism by which AAS use and exercise might complement each other. Resistance exercise itself increases androgen receptor mRNA and/or binding in both rodent and human muscle (Deschenes *et al.*, 1994; Bamman *et al.*, 2001). If androgen receptor number is induced in muscle by exercise, then more binding sites become available.

F. ROLE OF THE CENTRAL NERVOUS SYSTEM IN AAS EFFECTS ON STRENGTH

An increased sense of energy and wellbeing is one of the earliest and most frequently documented effects in hypogonadal men. It has been suggested that effects within the central nervous system (CNS) contribute to AAS effects on strength because AAS users feel more energetic and therefore train harder. Case reports, cross-sectional studies, and prospective, longitudinal studies show that AAS use by athletes can be accompanied by increased feelings of energy, aggressiveness, and elevated mood (Bahrke and Yesalis, 1996; Rubinow and Schmidt, 1996; Pope *et al.*, 2000). Effects of AAS typically focus on negative reports of psychotic symptoms and criminal aggressive behavior (Pope *et al.*, 1988, 2000; Uzych, 1992; Porcerelli and Sandler, 1998). However, two studies of high-dose androgen administration to normal volunteers reported increases in euphoria, energy, and sexual arousal, as well as several negative mood characteristics, including irritability, mood swings, violent feelings, and hostility (Hannan *et al.*, 1991; Su *et al.*, 1993). However, administration of supraphysiologic levels of testosterone did not change aggression as assessed with the Multi-Dimensional Anger Inventory in normal, eugonadal men (Tricker *et al.*, 1996). These few laboratory studies do not provide definitive answers to this question because they utilize controlled dosing of testosterone (although in the supraphysiologic range), employ a variety of methods for measuring aggression/

hostility, and use as subjects eugonadal men in laboratory settings rather than athletes in highly competitive settings who are self-administering even-higher doses of steroids. However, the frequency of case reports of extreme behaviors and positive findings in controlled studies suggest that AAS might influence strength through effects on behavior.

The mechanism by which the psychological effects of androgens occur is unknown. A study of cerebrospinal fluid (CSF) monoamine levels in a controlled study of high-dose methyltestosterone administration reported that levels of the serotonin metabolite 5HIAA were higher and levels of the norepinephrine metabolite MHPG were lower after methyltestosterone treatment. 5HIAA levels correlated negatively in subjects who experienced more negative mood symptoms (e.g., irritability, hostility) and higher 5HIAA in subjects who experienced increased mood symptoms such as euphoria (Daly *et al.*, 2001). The latter findings are consistent with a broad literature supporting an association between low serotonin and aggression/irritability/hostility (Lucki, 1998; Oquendo and Mann, 2000). Another study showed increases in aggression that correlated with changes in CSF dopamine metabolites (Hannan *et al.*, 1991).

Testosterone influences brain function by three mechanisms. It contributes to the differentiation of brain areas that regulate regulation of reproductive hormone secretion, sexual behavior, as well nonreproductive behaviors, including aggression (reviewed by Rubinow and Schmidt, 1996). While these organizational effects establish the anatomical basis for sex-specific behavior patterns, they do not contribute to the acute effects of AAS. Androgens also influence many neural functions through both classical genomic effects and rapid membrane effects. Androgen receptors are distributed (Simerly *et al.*, 1990; Pelletier, 2000) and likely have similar distributions in humans. AAS administration – at least in animal models – can increase androgen receptor number in some brain areas, just as it does in muscle (Lynch and Story, 2000). Effects on many neurotransmitter-specific proteins, including serotonin receptors, choline acetyltransferase, the rate-limiting synthetic enzyme for acetylcholine, and monoamine oxidase have been described (see review in Rubinow and Schmidt, 1996). These likely reflect changes in transcriptional activity but effects of suprapharmacologic doses are virtually unexplored.

Rapid membrane effects also may contribute to behavioral effects of AAS. Suprapharmacologic doses of AAS influence GABA receptor function acutely, over a timeframe that likely reflects rapid membrane rather than genomic effects. In some brain areas and model systems, AAS decrease GABA receptor function, while in others it increases it (Masonis and McCarthy, 1996; Jorge-Rivera *et al.*, 2000). Rapid changes in GABA function theoretically could contribute to disinhibition of behavior and changes in arousal like those reported in AAS users. A single recent report (Schlussman *et al.*, 2000) showed nandrolone caused

increases in corticotropin (ACTH) and corticosterone secretion acutely as well as protracted effects that were the reverse 24 hours later. This finding indicates that AAS influences at least one neuronal system related to stress and arousal exhibits through what may be both rapid and genomic effects.

Unfortunately, the question remains: do the behavioral effects of AAS influence training intensity and, therefore, muscle strength? Furthermore, although speculations abound that AAS improve neuromuscular function, this hypothesis has not been tested either.

The issue of AAS "dependence" reflects another widely publicized notion based on a small amount of data. Although not directly related to anabolic effects of AAS, a brief discussion is provided because this issue features prominently in discussion of AAS effects on behavior. Several studies report incidence of steroid "dependence" as reflected by psychological symptoms, including depressed mood, fatigue, anorexia, insomnia, restlessness, muscle and joint pain, depression, and desire to take more AAS when athletes stop using (Uzych, 1992; Bahrke and Yesalis, 1996). These reports – and the public perception that AAS use represented a public health crisis – led to the labeling of AAS as "addictive" drugs that were then scheduled by the Drug Enforcement Agency.

There are no clear data supporting the "addictiveness" of AAS use. This may reflect a lack of information or the fact that these drugs are not "addictive" in a neurobiologic sense. "Addictive drugs" must 1) be self-administered by humans and animals, 2) produce positive subjective effects, and 3) produce tolerance and dependence, manifested as a withdrawal syndrome when use stops. Other addictive drugs elicit positive subjective effects by activating the "reward" system in the brain, adaptation of which is thought to produce the gradual dysregulation of drug use (Wise, 1998). In a classical sense, anabolic steroids do not activate the reward system. They are not self-administered by animals and people cannot discriminate an injection of testosterone from placebo (see review in Lukas, 1996). It is impossible to conduct double-blind, placebo-controlled studies of long-term testosterone treatment on mood because users can usually recognize the active drug from the side effects. However, few AAS users fulfill psychiatric criteria for drug dependence (Lukas, 1996).

Nevertheless, some AAS users report positive feelings when they are taking drug and changes in mood when they stop (Su *et al.*, 1993; Lukas 1996). How does one reconcile the clinical reports with the laboratory studies? Genomic effects of AAS are delayed rather than immediate, so they would not be detected in any of the standard models of drug taking. It is possible that AAS do affect reward systems in the brain but in a delayed manner, as would be expected from a gonadal steroid, and so these effects have not been detected. Occasional reports of AAS effects on aspects of dopaminergic transmission, including upregulation of D1 receptors and increases in dopamine turnover, suggest that further explo-

ration of this possibility is warranted (Thiblin *et al.*, 1999; Kindlundh *et al.*, 2001).

VI. Other Consequences of Suprapharmacologic AAS Regimens

Androgen receptors are distributed throughout the body. Androgens affect behavior, cardiovascular function, reproduction, and other endocrine functions. Since anabolic actions are not easily dissociated pharmacologically from the other actions of testosterone derivatives, anabolic steroid use by athletes and patients inevitably is accompanied by unwanted side effects that result from the many actions of androgens in the body. During a typical high-dose paradigm, additional AAS effects occur, including 1) feedback inhibition of reproductive function, including decreased production of testosterone and sperm; 2) acne, due to stimulation of sebaceous glands in the skin; and 3) male-pattern hair distribution (Wilson, 1988). In addition, multiple effects on the cardiovascular system occur, including increased blood pressure, change in the ratio of blood lipids (decrease in HDL:LDL ratio), increased blood clotting, increased production of red blood cells, and left ventricular hypertrophy and subsequent decreased left ventricular function (Sullivan *et al.*, 1998). Extended discussion of potential mechanisms for these effects is beyond the scope of this review. However, the regular occurrence of these additional effects contradicts the common argument that AAS cannot be anabolic because androgen receptors are completely saturated at physiologic levels of androgen. The impact of these other systemic effects on the anabolic effects of AAS is unknown. Although increased production of red blood cells should theoretically improve oxygen-carrying capacity of the blood, and so the ability to do sustained work, these effects have not been documented in eugonadal men.

One final note about the use of AAS for their anabolic properties: when used in women, they produce a consistent pattern of virilizing side effects that are predictable, severe, and, in some cases, irreversible. The first published study (Strauss *et al.*, 1985) reported physical changes in the majority of a small group of AAS-using female athletes, including deepening of the voice, clitoral hypertrophy, menstrual irregularities, decreased body fat, and increased facial hair. Behavioral changes included increased libido, aggressiveness, and appetite. About half reported additional changes, including acne, breast size, and body hair distribution. A more recent study (Malarkey *et al.*, 1991) reported a 39% fall in HDL lipoprotein. All of these effects were reported more recently (Gruber and Pope, 2000) in a study involving a larger group. Some of these effects (e.g., deepening of the voice, clitoral hypertrophy) represent irreversible virilization, while others (e.g., reproductive effects, acne, blood lipids) are reversible. The consistency of these findings argues strongly that clinical trials for AAS use for anabolic purposes, as in burn patients, be conducted with great caution because there is no clinically available AAS that lacks androgenizing effects in women.

VII. Conclusions

Studies in AAS-using human subjects as well as experimental model systems have refuted the decades-old assertion that suprapharmacologic dose regimens of AAS are not anabolic in normal men or are only anabolic due to the impact of their CNS effects on motivation to train. The physiopathology of suprapharmacologic doses of AAS is clearly demonstrated and predicted by the beneficial effects on the same systems when AAS are used in hypogonadal men. However, there has been surprisingly little work on the mechanism by which these suprapharmacologic doses exert their actions or on pharmacologic strategies to distinguish beneficial (anabolic) effects from pathologic side effects on brain and heart. The recent demonstration of clinical benefits of suprapharmacologic regimens (Bhasin *et al.*, 1996,1997,1999,2001) suggests that such developments could be clinically beneficial. A recent review proposed the potential value of exploring the possible tissue specificity of protein regulators of androgen receptor function, comparable to those which have been exploited so successfully in the development of selective estrogen receptor modulators (Negro-Vilar, 1999).

THE EFFECTS OF SUPRAPHYSIOLOGIC DOSES OF TESTOSTERONE ON MUSCLE SIZE AND STRENGTH IN NORMAL MEN

SHALENDER BHASIN, M.D., THOMAS W. STORER, PH.D., NANCY BERMAN, PH.D., CARLOS CALLEGARI, M.D.,
BRENDA CLEVINGER, B.A., JEFFREY PHILLIPS, M.D., THOMAS J. BUNNELL, B.A., RAY TRICKER, PH.D., AIDA SHIRAZI, R.PH.,
AND RICHARD CASABURI, PH.D., M.D.

ABSTRACT

Background Athletes often take androgenic steroids in an attempt to increase their strength. The efficacy of these substances for this purpose is unsubstantiated, however.

Methods We randomly assigned 43 normal men to one of four groups: placebo with no exercise, testosterone with no exercise, placebo plus exercise, and testosterone plus exercise. The men received injections of 600 mg of testosterone enanthate or placebo weekly for 10 weeks. The men in the exercise groups performed standardized weight-lifting exercises three times weekly. Before and after the treatment period, fat-free mass was determined by underwater weighing, muscle size was measured by magnetic resonance imaging, and the strength of the arms and legs was assessed by bench-press and squatting exercises, respectively.

Results Among the men in the no-exercise groups, those given testosterone had greater increases than those given placebo in muscle size in their arms (mean [\pm SE] change in triceps area, 424 ± 104 vs. -81 ± 109 mm²; $P < 0.05$) and legs (change in quadriceps area, 607 ± 123 vs. -131 ± 111 mm²; $P < 0.05$) and greater increases in strength in the bench-press (9 ± 4 vs. -1 ± 1 kg, $P < 0.05$) and squatting exercises (16 ± 4 vs. 3 ± 1 kg, $P < 0.05$). The men assigned to testosterone and exercise had greater increases in fat-free mass (6.1 ± 0.6 kg) and muscle size (triceps area, 501 ± 104 mm²; quadriceps area, 1174 ± 91 mm²) than those assigned to either no-exercise group, and greater increases in muscle strength (bench-press strength, 22 ± 2 kg; squatting-exercise capacity, 38 ± 4 kg) than either no-exercise group. Neither mood nor behavior was altered in any group.

Conclusions Supraphysiologic doses of testosterone, especially when combined with strength training, increase fat-free mass and muscle size and strength in normal men. (N Engl J Med 1996;335:1-7.)

©1996, Massachusetts Medical Society.

ANABOLIC-ANDROGENIC steroids are widely abused by athletes and recreational bodybuilders because of the perception that these substances increase muscle mass and strength,¹⁻⁹ but this premise is unsubstantiated. Testosterone replacement increases nitrogen retention and fat-free mass in castrated animals and hypogonadal men,¹⁰⁻¹⁵ but whether supraphysiologic doses of testosterone or other anabolic-androgenic steroids augment muscle mass and strength in normal men is unknown.¹⁻⁹ Studies of the effects of such steroids on muscle strength have been inconclusive,¹⁶⁻³³ and several reviews have emphasized the shortcomings of the studies.^{1-5,8-10} Some of the studies were not randomized; most did not control for intake of energy and protein; the exercise stimulus was often not standardized; and some studies included competitive athletes whose motivation to win may have kept them from complying with a standardized regimen of diet and exercise.

We sought to determine whether supraphysiologic doses of testosterone, administered alone or in conjunction with a standardized program of strength-training exercise, increase fat-free mass and muscle size and strength in normal men. To overcome the pitfalls of previous studies, the intake of energy and protein and the exercise stimulus were standardized. Because some previous studies had demonstrated significant increases in muscle strength and hyper-

trophy in experienced athletes but not in sedentary subjects, we studied men who had weight-lifting experience.

METHODS

Study Design

This study was approved by the institutional review boards of the Harbor-UCLA Research and Education Institute and the Charles R. Drew University of Medicine and Science. All the study subjects gave informed written consent. The subjects were normal men weighing 90 to 115 percent of their ideal body weights; they were 19 to 40 years of age and had experience with weight lifting. They were recruited through advertisements in local newspapers and community colleges. None had participated in competitive sports in the preceding 12 months. Men who had ever taken anabolic agents or recreational drugs or had had a psychiatric or behavioral disorder were excluded from the study.

Of 50 men who were recruited, 7 dropped out during the control period because of problems with scheduling or compliance. The remaining 43 men were randomly assigned to one of four groups: placebo with no exercise, testosterone with no exercise, placebo plus exercise, and testosterone plus exercise. The study was divided into a 4-week control period, a 10-week treatment period, and a 16-week recovery period. During the four-week control period, the men were asked not to lift any weights or engage in strenuous aerobic exercise.

Of the 43 men, 3 dropped out during the treatment phase: 1 because of problems with compliance, 1 because illicit-drug use was detected by routine drug screening, and 1 because of an automobile accident. Forty men completed the study: 10 in the placebo, no-exercise group; 10 in the testosterone, no-exercise group; 9 in the placebo-plus-exercise group; and 11 in the testosterone-plus-exercise group.

Standardization of Protein and Energy Intake

Two weeks before day 1, the men were instructed to begin following a standardized daily diet containing 36 kcal per kilogram of body weight, 1.5 g of protein per kilogram, and 100 percent of the recommended daily allowance of vitamins, minerals, and trace elements. Compliance with the diet was verified every four weeks by three-day records of food consumption. The dietary intake was adjusted every two weeks on the basis of changes in body weight.

Treatment

The men received either 600 mg of testosterone enanthate in sesame oil or placebo intramuscularly each week for 10 weeks in the Clinical Research Center. This dose is six times higher than the dose usually given as replacement therapy in men with hypogonadism and is therefore supraphysiologic. Doses as high as 300 mg per week have been given to normal men for 16 to 24 weeks without major toxic effects.³⁴

Training Stimulus

The men in the exercise groups received controlled, supervised strength training three days per week during the treatment period. All the men trained at equivalent intensities in relation to their strength scores before the training. The training consisted of a cycle of weight lifting at heavy intensity (90 percent of the maximal weight the man lifted for one repetition before the start of training), light intensity (70 percent of the pretraining one-repetition maximal weight), and medium intensity (80 percent of this maximal weight) on three nonconsecutive days each week.³⁵ Regardless of the actual weights lifted, the training was held constant at four sets with six repetitions per set (a set is the number of complete repetitions of an exercise followed by rest). Because previous research had demonstrated increases in strength of ap-

proximately 7 percent for the bench-press exercise and 12 percent for the squatting exercise after four to five weeks of training,³⁵ the weights were increased correspondingly during the final five weeks of training in relation to the initial intensity. The number of sets was also increased from four to five, but the number of repetitions per set remained constant. The men were advised not to undertake any resistance exercise or moderate-to-heavy endurance exercise in addition to the prescribed regimen.

Evaluation and Outcome Measures

The primary end points were fat-free mass, muscle size as measured by magnetic resonance imaging (MRI), and muscle strength as based on the one-repetition maximal weight lifted during the bench-press and squatting exercises before and after the 10-week treatment period. Serum concentrations of total and free testosterone, luteinizing hormone, follicle-stimulating hormone, and sex hormone-binding globulin were measured on days 14 and 28 of the control period and days 2, 3, 7, 14, 28, 42, 56, and 70 of the treatment period. Blood counts, blood chemistry (including serum aminotransferases), serum concentrations of prostate-specific antigen, and plasma concentrations of total cholesterol, low-density lipoprotein (LDL) cholesterol, high-density lipoprotein (HDL) cholesterol, and triglycerides were measured at the start of the control period and on day 4; on days 28, 56, and 70 of the treatment period; and four months after the discontinuation of treatment. Periodic evaluations to identify adverse effects were performed by examiners unaware of the study-group assignments on days 1 and 28 of the control period; days 28, 56, and 70 of the treatment period; and four months after the discontinuation of treatment. Mood and behavior were evaluated during the first week of the control period and after 6 and 10 weeks of treatment. Sexual function and semen characteristics were not assessed.

Assessment of Muscle Size

Muscle size was measured by MRI of the arms and legs at the humeral or femoral mid-diaphyseal level, the junction of the upper third and middle third of the bone, and the junction of the middle third and lower third. The cross-sectional areas of the arms and legs, the subcutaneous tissue, the muscle compartment, and the quadriceps and triceps muscles were computed, and the areas at the three levels were averaged.

Analysis of Body Composition

Fat-free mass was estimated on the basis of measurements of body density obtained by underwater weighing. During weighing, the men were asked to exhale to the residual volume, as measured by helium dilution.

Measures of Muscle Strength

The effort-dependent performance of muscle was assessed on the basis of the maximal weight lifted for one repetition during the bench-press and squatting exercises.³⁶ Each man completed increasingly more difficult lifts with the same weights and bars that he used during training; in each exercise, the maximal weight lifted (the one-repetition maximum) was recorded as a measure of muscle strength.

Hormone Measurements

Serum concentrations of luteinizing hormone and follicle-stimulating hormone were measured by immunofluorometric assays,³⁶ each with a sensitivity of 0.05 IU per liter. Serum testosterone was measured by immunoassay,³⁷ and free testosterone was measured by equilibrium dialysis.³⁷ Serum concentrations of sex hormone-binding globulin and prostate-specific antigen were measured by immunoassays using reagents purchased from Delphia-Wallac (Turku, Finland) and Hybritech (San Diego, Calif.), respectively.

*Values at 10 weeks were obtained 1 week after the final injection. To convert values for total testosterone to nanomoles per liter, multiply by 0.0347; to convert values for free testosterone to picomoles per liter, multiply by 3.47; to convert values for sex hormone-binding globulin to nanomoles per liter, multiply by 0.12. Plus-minus values are means ±SE.

†P<0.001 for the comparison with the corresponding base-line value.

‡P<0.05 for the comparison of the difference between this value and the base-line value with the corresponding difference in either placebo group.

§P=0.008 for the comparison with the corresponding base-line value.

¶P=0.05 for the comparison with the corresponding base-line value.

groups, but not in the placebo groups (Table 3). The base-line serum concentrations of luteinizing hormone, follicle-stimulating hormone, and sex hormone-binding globulin were similar in the four groups, and the concentrations decreased significantly in the two testosterone groups.

Body Weight and Composition

Body weight did not change significantly in the men in either placebo group (Table 4). The men given testosterone without exercise had a significant mean increase in total body weight, and those in the testosterone-plus-exercise group had an average increase of 6.1 kg in body weight — a greater increase than in the other three groups.

Fat-free mass did not change significantly in the group assigned to placebo but no exercise (Table 4 and Fig. 1). The men treated with testosterone but no exercise had an increase of 3.2 kg in fat-free mass, and those in the placebo-plus-exercise group had an increase of 1.9 kg. The increase in the testosterone-plus-exercise group was substantially greater (averaging 6.1 kg). The percentage of body fat did not change significantly in any group (data not shown).

Muscle Size

The mean cross-sectional areas of the arm and leg muscles did not change significantly in the placebo

groups, whether the men had exercise or not (Table 4 and Fig. 1). The men in the testosterone groups had significant increases in the cross-sectional areas of the triceps and the quadriceps (Table 4); the group assigned to testosterone without exercise had a significantly greater increase in the cross-sectional area of the quadriceps than the placebo-alone group, and the testosterone-plus-exercise group had greater increases in quadriceps and triceps area than either the testosterone-alone or the placebo-plus-exercise group (P<0.05).

Muscle Strength

Muscle strength in the bench-press and the squatting exercises did not change significantly over the 10-week period in the group assigned to placebo with no exercise. The men in the testosterone-alone and placebo-plus-exercise groups had significant increases in the one-repetition maximal weights lifted in the squatting exercises, averaging 19 percent and 21 percent, respectively (Table 4 and Fig. 1). Similarly, mean bench-press strength increased in these two groups by 10 percent and 11 percent, respectively. In the testosterone-plus-exercise group, the increase in muscle strength in the squatting exercise (38 percent) was greater than that in any other group, as was the increase in bench-press strength (22 percent).

† $P < 0.05$ for the comparison of the change from base line with that in either placebo group.

‡ $P < 0.05$ for the comparison of the change from base line with that in either no-exercise group.

§ $P < 0.05$ for the comparison of the change from base line with that in the group assigned to placebo with no exercise.

¶ $P < 0.05$ for the comparison of the change from base line with that in the other three groups.

Mood and Behavior

No differences were found between the exercise groups and the no-exercise groups or between the placebo groups and the testosterone groups in any of the five subcategories of anger assessed by the Multidimensional Anger Inventory. No significant changes in mood or behavior were reported by the men on the Mood Inventory or by their live-in partners, spouses, or parents on the Observer Mood Inventory.

DISCUSSION

Our results show that supraphysiologic doses of testosterone, especially when combined with strength training, increase fat-free mass, muscle size, and strength in normal men when potentially confounding variables, such as nutritional intake and exercise stimulus, are standardized. The combination of strength training and testosterone produced greater increases in muscle size and strength than were achieved with either intervention alone. The combined regimen of testosterone and exercise led to an increase of 6.1 kg in fat-free mass over the course of

10 weeks; this increase entirely accounted for the changes in body weight.

The exercise was standardized in all the men, and therefore the effects of testosterone on muscle size and strength cannot be attributed to more intense training in the groups receiving the treatment. Careful selection of experienced weight lifters, the exclusion of competitive athletes, and close follow-up ensured a high degree of compliance with the regimens of exercise, treatment, and diet, which was verified by three-day food records (data not shown) and the values obtained for serum testosterone, luteinizing hormone, and follicle-stimulating hormone. Except for one man who missed one injection, all the men received all their scheduled injections. It has been argued that studies in which large doses of androgens are used cannot be truly blinded because of the occurrence of acne or other side effects. In this study, neither the investigators nor the personnel performing the measurements knew the study-group assignments. Three men receiving testosterone and one man receiving placebo had acneiform eruptions; these men may have assumed themselves to be receiving testosterone. Thus, it cannot be stated with certainty

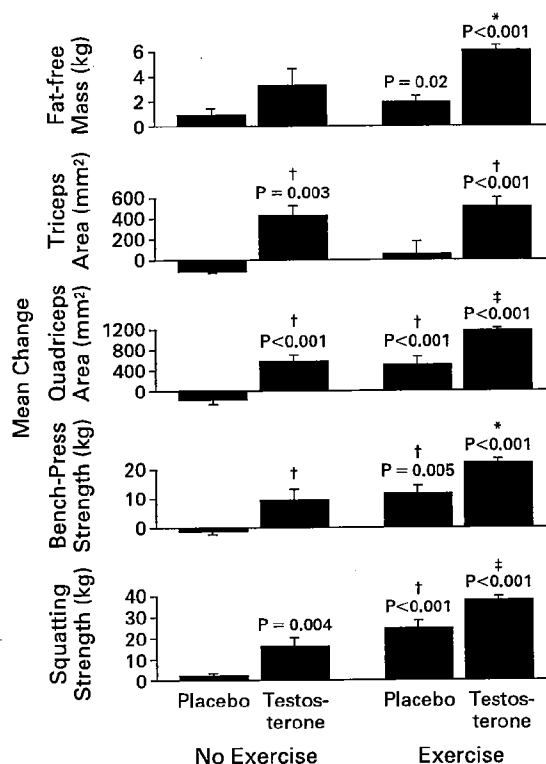

Figure 1. Changes from Base Line in Mean (\pm SE) Fat-free Mass, Triceps and Quadriceps Cross-Sectional Areas, and Muscle Strength in the Bench-Press and Squatting Exercises over the 10 Weeks of Treatment.

The P values shown are for the comparison between the change indicated and a change of zero. The asterisks indicate $P < 0.05$ for the comparison between the change indicated and that in either no-exercise group; the daggers, $P < 0.05$ for the comparison between the change indicated and that in the group assigned to placebo with no exercise; and the double daggers, $P < 0.05$ for the comparison between the change indicated and the changes in all three other groups.

that the men were completely unaware of the nature of their treatments.

The doses of androgenic steroids used in previous studies were low,^{1-5,11,12} mostly because of concern about potential toxic effects. In contrast, to our knowledge the dose of testosterone enanthate administered in this study (600 mg per week) is the highest administered in any study of athletic performance. Undoubtedly, some athletes and bodybuilders take even higher doses than those we gave. Furthermore, athletes often "stack" androgenic and anabolic steroids, taking multiple forms simultaneously. We do not know whether still higher doses of testosterone or the simultaneous administration of several steroids would have more pronounced effects. The absence of systemic toxicity during tes-

tosterone treatment was consistent with the results of studies of the contraceptive efficacy of that hormone.³⁴

The method used in this study to evaluate muscle performance on the basis of the one-repetition maximal weight lifted is dependent on effort. Although the men receiving testosterone did have increases in muscle size, some of the gains in strength may have resulted from the behavioral effects of testosterone.

The dose dependency of the action of testosterone on fat-free mass and protein synthesis has not been well studied. Forbes³⁹ proposed a single dose-response curve extending from the hypogonadal to the supraphysiologic range. Others have suggested that there may be two dose-response curves: one in the hypogonadal range, with maximal responses corresponding to the serum testosterone concentrations at the lower end of the range in normal men, and the second in the supraphysiologic range, presumably representing a separate mechanism of action—that is, a pathway of independent androgen receptors.^{1,40}

Supraphysiologic doses of testosterone, with or without exercise, did not increase the occurrence of angry behavior by these carefully selected men in the controlled setting of this experiment. Our results, however, do not preclude the possibility that still higher doses of multiple steroids may provoke angry behavior in men with preexisting psychiatric or behavioral problems.

Our results in no way justify the use of anabolic-androgenic steroids in sports, because, with extended use, such drugs have potentially serious adverse effects on the cardiovascular system, prostate, lipid metabolism, and insulin sensitivity. Moreover, the use of any performance-enhancing agent in sports raises serious ethical issues. Our findings do, however, raise the possibility that the short-term administration of androgens may have beneficial effects in immobilized patients, during space travel, and in patients with cancer-related cachexia, disease caused by the human immunodeficiency virus, or other chronic wasting disorders.

Supported by a grant (1 RO1 DK 45211) from the National Institutes of Health, by a General Clinical Research Center grant (MO-00543), and by grants (P20RR11145-01, a Clinical Research Infrastructure Initiative; and G12RR03026) from the Research Centers for Minority Institutions.

We are indebted to Dr. Indrani Sinha-Hikim for the serum hormone assays, to Dr. Paul Fu for the plasma lipid measurements, to the staff of the General Clinical Research Center for conducting the studies, and to BioTechnology General Corporation, Iselin, New Jersey, for providing testosterone enanthate.

Yarasheski, Lynne Magliano, Connie Dzekov, Jeanne Dzekov, Rachelle Bross, Jeffrey Phillips, Indrani Sinha-Hikim, Ruoqing Shen, and Thomas W. Storer. Testosterone dose-response relationships in healthy young men. *Am J Physiol Endocrinol Metab* 281: E1172–E1181, 2001.—Testosterone increases muscle mass and strength and regulates other physiological processes, but we do not know whether testosterone effects are dose dependent and whether dose requirements for maintaining various androgen-dependent processes are similar. To determine the effects of graded doses of testosterone on body composition, muscle size, strength, power, sexual and cognitive functions, prostate-specific antigen (PSA), plasma lipids, hemoglobin, and insulin-like growth factor I (IGF-I) levels, 61 eugonadal men, 18–35 yr, were randomized to one of five groups to receive monthly injections of a long-acting gonadotropin-releasing hormone (GnRH) agonist, to suppress endogenous testosterone secretion, and weekly injections of 25, 50, 125, 300, or 600 mg of testosterone enanthate for 20 wk. Energy and protein intakes were standardized. The administration of the GnRH agonist plus graded doses of testosterone resulted in mean nadir testosterone concentrations of 253, 306, 542, 1,345, and 2,370 ng/dl at the 25-, 50-, 125-, 300-, and 600-mg doses, respectively. Fat-free mass increased dose dependently in men receiving 125, 300, or 600 mg of testosterone weekly (change +3.4, 5.2, and 7.9 kg, respectively). The changes in fat-free mass were highly dependent on testosterone dose ($P = 0.0001$) and correlated with log testosterone concentrations ($r = 0.73$, $P = 0.0001$). Changes in leg press strength, leg power, thigh and quadriceps muscle volumes, hemoglobin, and IGF-I were positively correlated with testosterone concentrations, whereas changes in fat mass and plasma high-density lipoprotein (HDL) cholesterol were negatively correlated. Sexual function, visual-spatial cognition and mood, and PSA levels did not change significantly at any

dose. We conclude that changes in circulating testosterone concentrations, induced by GnRH agonist and testosterone administration, are associated with testosterone dose- and concentration-dependent changes in fat-free mass, muscle size, strength and power, fat mass, hemoglobin, HDL cholesterol, and IGF-I levels, in conformity with a single linear dose-response relationship. However, different androgen-dependent processes have different testosterone dose-response relationships.

sexual function; testosterone effects on muscle; cognitive function; plasma lipids; prostate-specific antigen; testosterone effects on insulin-like growth factor I; testosterone and hemoglobin

TESTOSTERONE regulates many physiological processes, including muscle protein metabolism, some aspects of sexual and cognitive functions, secondary sex characteristics, erythropoiesis, plasma lipids, and bone metabolism (7, 50). However, testosterone dose dependency of various androgen-dependent processes is not well understood (6). Administration of replacement doses of testosterone to hypogonadal men (10, 12, 30, 45, 49) and of supraphysiological doses to eugonadal men (9, 22–23, 26) increases fat-free mass, muscle size, and strength. Conversely, suppression of endogenous testosterone concentrations is associated with loss of fat-free mass and a decrease in fractional muscle protein synthesis (33). However, not known are whether testosterone effects on the muscle are dose dependent, or the nature of the testosterone dose-response relationships (6). Androgen receptors in most tissues are either saturated or downregulated at physiological testosterone concentrations (2, 18, 39, 50); this leads to speculation that there might be two separate dose-response curves: one in hypogonadal range, with

maximal response at low normal testosterone concentrations, and a second in supraphysiological range, representing a separate mechanism of action (1). However, testosterone dose-response relationships for a range of androgen-dependent functions in humans have not been studied.

Animal studies suggest that different androgen-dependent processes have different androgen dose-response relationships (6, 8, 21). Sexual function in male mammals is maintained at serum testosterone concentrations that are at the lower end of the male range (3, 6, 8, 13, 21, 31). However, it is not known whether the low normal testosterone levels that normalize sexual function are sufficient to maintain muscle mass and strength, or whether the higher testosterone concentrations required to maintain muscle mass and strength might adversely affect plasma lipids, hemoglobin levels, and the prostate. This information is important for optimizing testosterone replacement regimens for treatment of hypogonadal men. Also, for the proposed use of testosterone in sarcopenia associated with aging (46, 47) and chronic illness (11, 27), it is important to know whether significant gains in muscle mass and strength can be achieved at testosterone doses that do not adversely affect plasma high-density lipoprotein (HDL) and prostate-specific antigen (PSA) levels.

Therefore, the primary objective of this study was to determine the dose dependency of testosterone's effects on fat-free mass and muscle performance. We hypothesized that changes in circulating testosterone concentrations would be associated with dose-dependent changes in fat-free mass, muscle strength, and power in conformity with a single linear dose-response relationship, and that the dose requirements for maintaining other androgen-dependent processes would be different. We treated young men with a long-acting gonadotropin-releasing hormone (GnRH) agonist to suppress endogenous testosterone secretion, and concomitantly also with one of five testosterone-dose regimens to create different levels of serum testosterone concentrations extending from subphysiological to the supraphysiological range. The lowest testosterone dose, 25 mg weekly, was selected because this dose had been shown to maintain sexual function in GnRH antagonist-treated men (37). The selection of the 600-mg weekly dose was based on the consideration that this was the highest dose that had been safely administered to men in controlled studies (9).

METHODS

This was a double-blind, randomized study consisting of a 4-wk control period, a 20-wk treatment period, and a 16-wk recovery period. Each participant provided informed consent, approved by the institutional review boards of Drew University and Harbor-UCLA Research and Education Institute.

Participants. The participants were healthy men, 18–35 yr of age, with prior weight-lifting experience and normal testosterone levels. These men had not used any anabolic agents and had not participated in competitive sports events in the

preceding year, and they were not planning to participate in competitive events in the following year.

Randomization. Sixty-one eligible men were randomly assigned to one of five groups. All received monthly injections of a long-acting GnRH agonist to suppress endogenous testosterone production. In addition, *group 1* received 25 mg of testosterone enanthate intramuscularly weekly; *group 2*, 50 mg testosterone enanthate; *group 3*, 125 mg testosterone enanthate; *group 4*, 300 mg testosterone enanthate; and *group 5*, 600 mg testosterone enanthate. Twelve men were assigned to *group 1*, 12 to *group 2*, 12 to *group 3*, 12 to *group 4*, and 13 to *group 5*. Testosterone and GnRH agonist injections were administered by the General Clinical Research Center staff to assure compliance.

Nutritional intake. Energy and protein intakes were standardized at 36 kcal·kg⁻¹·day⁻¹ and 1.2 g·kg⁻¹·day⁻¹, respectively. The standardized diet was initiated 2 wk before treatment was started; dietary instructions were reinforced every 4 wk. The nutritional intake was verified by analysis of 3-day food records and 24-h food recalls every 4 wk by use of the Minnesota Nutritional Software.

Exercise stimulus. The participants were asked not to undertake strength training or moderate-to-heavy endurance exercise during the study. These instructions were reinforced every 4 wk.

Outcome measures. Body composition and muscle performance were assessed at baseline and during *week 20*. Fat-free mass and fat mass were measured by underwater weighing and dual-energy X-ray absorptiometry (DEXA, Hologic 4500, Waltham, MA). Total thigh muscle and quadriceps muscle volumes were measured by MRI scanning.

For estimation of total body water, the men ingested 10 g of ²H₂O (10, 11), and plasma samples were drawn at -15, 0, 120, 180, and 240 min. We measured ²H abundance in plasma by nuclear magnetic resonance spectroscopy (10, 11), with a correction factor of 0.985 for exchangeable hydrogen. We measured bilateral leg press strength by use of the one-repetition maximum (1-RM) method (11). A seated leg press exercise with pneumatic resistance (Keiser Sport, Fresno, CA) was used for this purpose. Subjects performed 5–10 min of leg cycling and stretching warm-up and received instruction and practice in lifting mechanics before performing progressive warm-up lifts leading to the 1-RM. Seat position and the ensuing knee and hip angles, as well as foot placement, were measured and recorded for use in subsequent testing. To ensure reliability in this highly effort-dependent test, the 1-RM score was reassessed within 7 days, but not sooner than 2 days, after the first evaluation. If duplicate scores were within 5%, the higher of the two values was accepted as the strength score. If the two tests differed by >5%, additional studies were conducted, ≥2 days apart but within 7 days, until the two highest scores were within 5%. No subject required >2 days of strength assessment.

We also measured leg power, because power in the lower extremity is strongly related to performance of functional activities in the elderly (4). The sarcopenia that accompanies aging is due in large part to a loss of the fast-twitch type II fibers and the coincident decrease in explosive force. Muscular power is important in performing such daily activities as rising from a chair, climbing stairs, and walking with speed (4). Leg power was measured with a previously validated (4, 5) Nottingham leg extensor power rig. Subjects performed 10–15 trials of right leg and hip extension, attempting to generate as much force as possible by accelerating the leg rig's weighted flywheel from rest. The power score (in watts) was taken as the highest value observed during these trials with evidence of a plateau. As with the strength tests, power

measurements were preceded by a 5- to 10-min warm-up, stretching, and practice. The power tests were repeated within 7 days, but not sooner than 2 days, after the first tests to reduce the effect of familiarization. To minimize test-retest variability, the angle of knee flexion and the seat position were recorded and maintained constant across tests.

Sexual function was assessed by daily logs of sexual activity and desire that were maintained for 7 consecutive days at baseline and during treatment by use of a published instrument (13). Spatial cognition was assessed by a computerized checkerboard test (38) and mood by Hamilton's depression (20) and Young's mania scales (24).

Adverse experiences, blood counts and chemistries, PSA, plasma lipids, total and free testosterone, luteinizing hormone (LH), sex steroid-binding globulin (SHBG), and insulin-like growth factor I (IGF-I) levels were measured periodically during control and treatment periods. Serum total testosterone was measured by an immunoassay (8–11); free testosterone by equilibrium dialysis (43); LH, SHBG, and PSA by immunoradiometric assays (9–11); and IGF-I by acid-ethanol extraction and immunoassay (28). The sensitivities and intra- and interassay coefficients of variation for hormone assays were as follows: total testosterone (0.6 ng/dl), 8.2 and 13.2%; free testosterone (0.22 pg/ml), 4.2 and 12.3%; LH (0.05 U/l), 10.7 and 13.0%; SHBG (6.25 nmol/l), 4 and 6%; PSA (0.01 ng/ml), 5.0 and 6.4%; and IGF-I (80 ng/ml), 4 and 6%, respectively. These assays have been validated previously (8–11).

Statistical analyses. All variables were examined for their distribution characteristics. Variables not meeting the assumption of a normal distribution were log-transformed and retested. An ANOVA was used to compare change from baseline in outcome measures among the five groups. All outcome measures were analyzed using a paired *t*-test to detect a nonzero change from baseline within each group. $P < 0.05$ was considered statistically significant.

To describe the relationship between testosterone concentrations (T) and change in fat-free mass (Y) during testosterone administration, we tested three models: a linear model ($Y = a + bT$); a logarithmic model, $Y = a + b \cdot X$, where $X = \log(T)$, and a and b represent the intercept and slope, respectively; and a growth model, $Y = a/(1 + b \cdot e^{-k \cdot X})$. The logarithmic model provided the best fit for the data and was used to model the effects of testosterone concentrations on the change in other outcome variables. The correlations between testosterone concentrations and change in outcome variables are derived from this model. We also modeled the linear dependence of the change in outcome variables on testosterone dose by use of linear regression.

RESULTS

Participant characteristics. Of 61 men enrolled, 54 completed the study: 12 in group 1, 8 in group 2, 11 in group 3, 10 in group 4, and 13 in group 5. One man discontinued treatment because of acne; other subjects were unable to meet the demands of the protocol. The five groups did not significantly differ with respect to their baseline characteristics (Table 1).

Compliance. All evaluable subjects received 100% of their GnRH agonist injections, and only one man in the 125-mg group missed one testosterone injection.

Nutritional intake. Daily energy intake and proportion of calories derived from protein, carbohydrate, and fat were not significantly different among the five groups at baseline. There was no significant change in daily caloric, protein, carbohydrate, or fat intake in any group during treatment (data not shown).

Hormone levels. Serum total and free testosterone levels (Table 2), measured during week 16, 1 wk after the previous injection, were linearly dependent on the testosterone dose ($P = 0.0001$). Serum total and free testosterone concentrations decreased from baseline in men receiving the 25- and 50-mg doses and increased at 300- and 600-mg doses. Serum LH levels were suppressed in all groups. Serum SHBG levels decreased dose dependently at the 300- and 600-mg doses but did not change in other groups. Serum IGF-I concentrations increased dose dependently at the 300- and 600-mg doses (correlation between log testosterone level and change in IGF-I = 0.55, $P = 0.0001$). IGFBP-3 levels did not change significantly in any group.

Body composition. Fat-free mass, measured by underwater weighing, did not change significantly in men receiving the 25- or 50-mg testosterone dose, but it increased dose dependently at higher doses (Table 3). The changes in fat-free mass were highly dependent on testosterone dose ($P = 0.0001$) and correlated with log total testosterone concentrations during treatment ($r = 0.73$, $P = 0.0001$, see Fig. 2).

Changes in fat-free mass, measured by DEXA scan, were qualitatively similar to those obtained from underwater weighing (Table 3, Fig. 1). The measurements of fat-free mass by DEXA were highly correlated with values obtained from underwater weighing ($r = 0.94$, $P < 0.0001$).

Table 1. Baseline characteristics of the participants

| GnRH Agonist Testosterone Enanthate | + | + | + | + | + | P Value |

| 50 mg | 246 ± 14 | 225 ± 12 | -20 ± 10 | 0.0797 |
| 125 mg | 299 ± 24 | 282 ± 31 | -18 ± 17 | 0.3284 |
| 300 mg | 314 ± 24 | 388 ± 30 | 74 ± 28 | 0.0272 |
| 600 mg | 227 ± 20 | 304 ± 21 | 77 ± 13 | 0.0001 |

Values on each day represent the mean (±SE) of all available values on that day. However, the change represents the difference between paired values only. Treatment values represent the day 113 (week 16) values, obtained 1 wk after the previous testosterone injection. We used week 16 rather than week 20 values because week 20 values were not always drawn exactly 1 wk after the previous injection. LH and FSH, luteinizing and follicle-stimulating hormones, respectively; SHBG, sex hormone-binding globulin; IGF-I, insulin-like growth factor I. To convert total testosterone levels to nmol/l, multiply by 0.03467. To convert free testosterone levels to pg/ml, multiply by 3.467.

To determine whether the apparent changes in fat-free mass by DEXA scan and underwater weighing represented water retention, we measured total body water and compared the ratios of total body water to fat-free mass before and after treatment in each group. The ratios of total body water to fat-free mass by underwater weighing did not significantly change with treatment in any treatment group (Table 3), indicating that the apparent increase in fat-free mass measured by underwater weighing did not represent water retention in excess of that associated with protein accretion.

Fat mass, measured by underwater weighing, increased significantly in men receiving the 25- and 50-mg doses but did not change in men receiving the higher doses of testosterone (Table 3, Fig. 1). There was an inverse correlation between change in fat mass

by underwater weighing and log testosterone concentrations ($r = -0.60$, $P = 0.0001$, Fig. 2).

Muscle size. The thigh muscle volume and quadriceps muscle volume did not significantly change in men receiving the 25- or 50-mg doses but increased dose dependently at higher doses of testosterone (Table 4, Fig. 1). The changes in thigh muscle and quadriceps muscle volumes correlated with log testosterone levels during treatment ($r = 0.66$, $P = 0.0001$, and $r = 0.55$, $P = 0.0001$, respectively, Fig. 2).

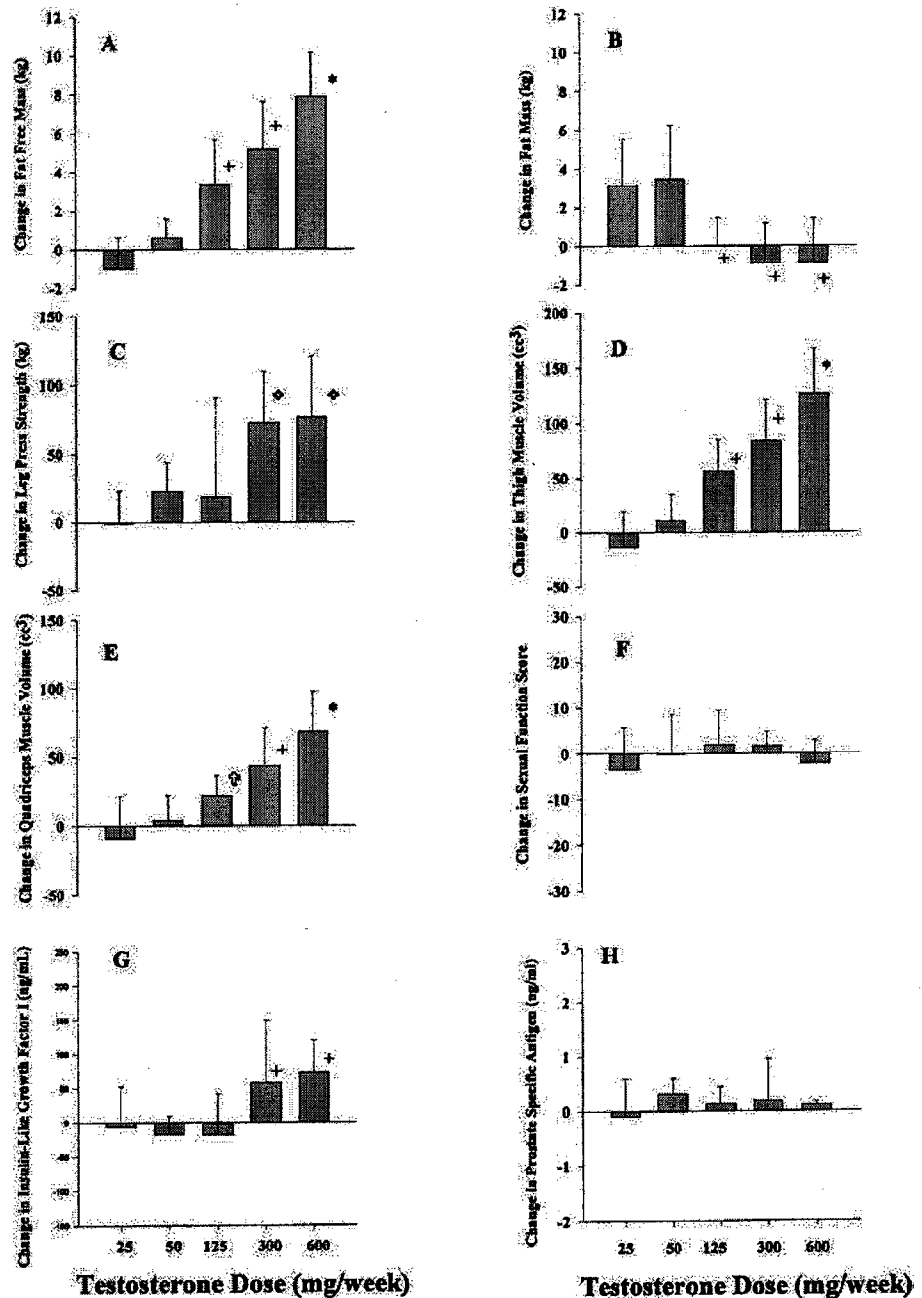

Muscle performance. The leg press strength did not change significantly in the 25- and 125-mg-dose groups but increased significantly in those receiving the 50-, 300-, and 600-mg doses (Table 5). The changes in leg press strength correlated with log testosterone levels during treatment ($r = 0.48$, $P = 0.0005$, Fig. 2) and changes in muscle volume ($r = 0.54$, $P = 0.003$) and fat-free mass ($r = 0.74$, $P < 0.0001$).

Table 3. Body composition analysis

| Testosterone Dose | Baseline | Week 20 | Change from Baseline | P vs. Zero Change |

| 125 mg | 67.0 ± 1.7 | 63.5 ± 3.0 | -3.8 ± 1.6 | |
| 300 mg | 61.6 ± 2.7 | 64.6 ± 3.1 | +2.1 ± 2.5 | |
| 600 mg | 65.3 ± 2.4 | 67.4 ± 2.8 | +2.5 ± 1.7 | |

Values on each day represent the mean (±SE) of all available values on that day. However, the change represents the difference between paired values only. Ratios of total body water assessed by deuterium water dilution to fat-free mass measured by underwater weighing were calculated for each subject and averaged across subjects within each group. DEXA, dual-energy X-ray absorptiometry.

Fig. 1. Change in fat-free mass (A), fat mass (B), leg press strength (C), thigh muscle volume (D), quadriceps muscle volume (E), sexual function (F), insulin-like growth factor I (G), and prostate-specific antigen (H). Data are means \pm SE. *Significant differences from all other groups ($P < 0.05$); \diamond significant difference from 25-, 50-, and 125-mg doses ($P < 0.05$); + significant difference from 25- and 50-mg doses ($P < 0.05$); and \dagger significant difference from 25-mg dose ($P < 0.05$).

Leg power, measured by the Nottingham leg rig, did not change significantly in men receiving the 25-, 50-, and 125-mg doses of testosterone weekly, but it increased significantly in those receiving the 300- and 600-mg doses. The increase in leg power correlated with log testosterone concentrations ($r = 0.39$, $P = 0.0105$, Fig. 2) and changes in fat-free mass ($r = 0.30$, $P = 0.0392$) and muscle strength ($r = 0.42$, $P = 0.0020$).

Behavioral measures. The scores for sexual activity and sexual desire measured by daily logs did not change significantly at any dose. Similarly, visual-

spatial cognition (Table 6) and mood, as assessed by Hamilton's depression and Young's manic scales (data not shown), did not change significantly in any group.

Adverse experiences and safety measures. Hemoglobin levels decreased significantly in men receiving the 50-mg dose but increased at the 600-mg dose; the changes in hemoglobin were positively correlated with testosterone concentrations ($r = 0.66$, $P = 0.0001$) (Table 7). Changes in plasma HDL cholesterol, in contrast, were negatively dependent on testosterone dose ($P = 0.0049$) and correlated with testosterone concentrations ($r =$

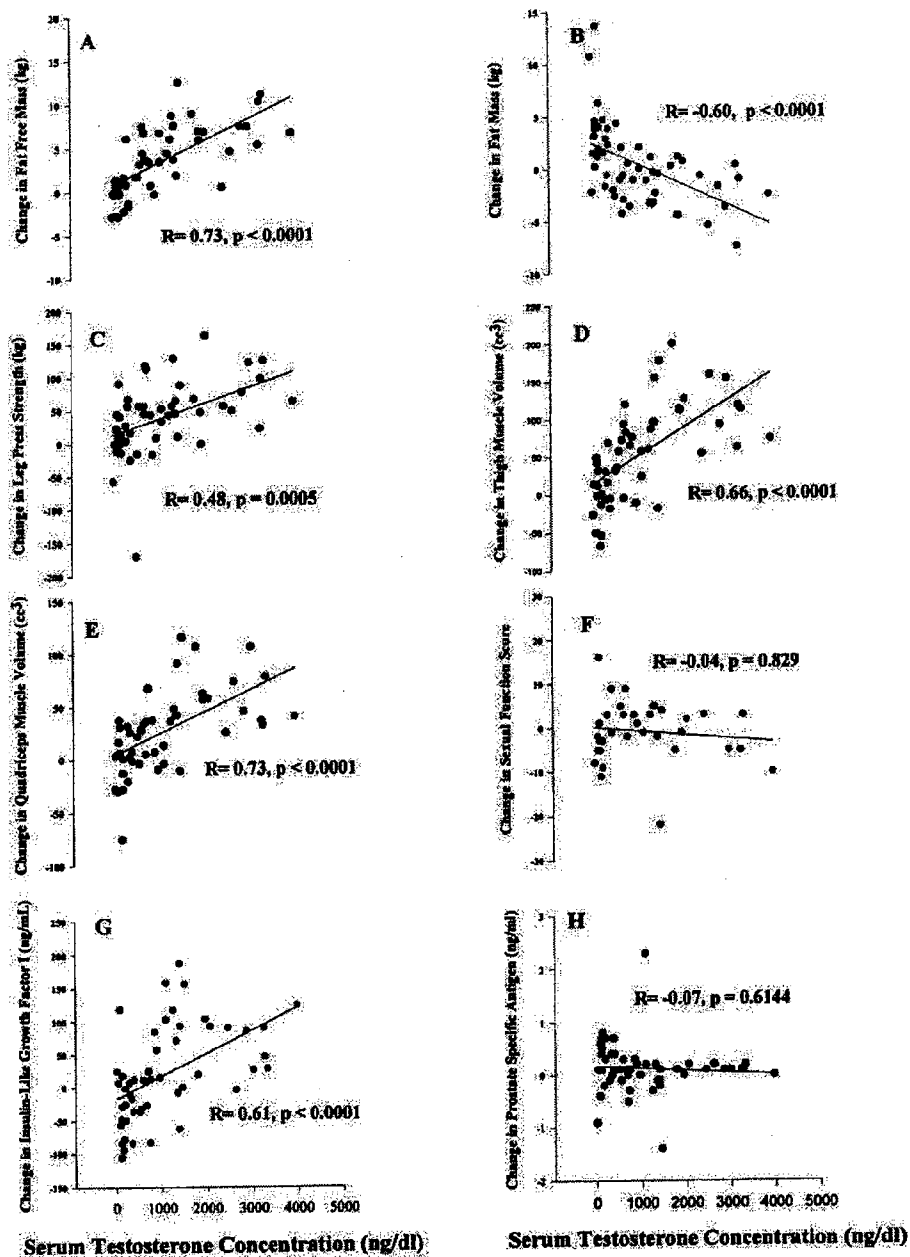

Fig. 2. Relationship between serum testosterone concentrations (T) during treatment (week 16) and change in fat-free mass (A), fat mass (B), leg press strength (C), thigh muscle volume (D), quadriceps muscle volume (E), sexual function (F), insulin-like growth factor I (G), and prostate-specific antigen (H). The correlation coefficient, r , was calculated using the logarithmic model, $Y = a + b \cdot X$, where $X = \log(T)$, and a and b represent the intercept and slope.

$-0.40, P = 0.0054$). Total cholesterol, plasma low-density lipoprotein cholesterol, and triglyceride levels did not change significantly at any dose. Serum PSA, creatinine, bilirubin, alanine aminotransferase, and alkaline phosphatase did not change significantly in any group, but aspartate aminotransferase decreased significantly in the 25-mg group. Two men in the 25-mg group, five in the 50-mg group, three in the 125-mg group, seven in the 300-mg group, and two in the 600-mg group developed acne. One man receiving the 50-mg dose reported decreased ability to achieve erections.

DISCUSSION

GnRH agonist administration suppressed endogenous LH and testosterone secretion; therefore, circulating testosterone concentrations during treatment were proportional to the administered dose of testosterone enanthate. This strategy of combined administration of GnRH agonist and graded doses of testosterone enanthate was effective in establishing different levels of serum testosterone concentrations among the five treatment groups. The different levels of circulating testosterone concentrations created by this regimen were associated with dose- and concentration-

Table 4. *Thigh and quadriceps muscle volume measured by MRI*

| Testosterone Dose | Baseline | Week 20 | Change from Baseline | P vs. zero change |
|--|----------|----------|----------------------|-------------------|
| <i>Thigh muscle volume (overall ANOVA P = 0.0001)</i> | | | | |
| 25 mg | 753 ± 46 | 739 ± 44 | -14 ± 10 | 0.1958 |
| 50 mg | 833 ± 53 | 844 ± 58 | 11 ± 8 | 0.2332 |
| 125 mg | 890 ± 49 | 966 ± 60 | 56 ± 10 | 0.0004 |
| 300 mg | 849 ± 39 | 933 ± 39 | 84 ± 12 | 0.0001 |
| 600 mg | 802 ± 45 | 928 ± 48 | 126 ± 12 | 0.0001 |
| <i>Quadriceps muscle volume (overall ANOVA P = 0.0001)</i> | | | | |
| 25 mg | 436 ± 30 | 427 ± 27 | -9 ± 9 | 0.3524 |
| 50 mg | 489 ± 34 | 493 ± 36 | 4 ± 7 | 0.5889 |
| 125 mg | 508 ± 29 | 546 ± 36 | 21 ± 5 | 0.0027 |
| 300 mg | 497 ± 25 | 540 ± 22 | 43 ± 9 | 0.0008 |
| 600 mg | 472 ± 27 | 540 ± 31 | 68 ± 8 | 0.0001 |

Values (in cm³) on each day represent the mean (±SE) of all available values on that day. However, the change represents the difference between paired values only.

dependent changes in fat-free mass, fat mass, thigh and quadriceps muscle volume, muscle strength, leg power, hemoglobin, circulating IGF-I, and plasma HDL cholesterol. Serum PSA levels, sexual desire and activity, and spatial cognition did not change significantly at any dose. The changes in fat-free mass, muscle volume, leg press strength and power, hemoglobin, and IGF-I were positively correlated, whereas changes in plasma HDL cholesterol and fat mass were negatively correlated with testosterone dose and total and free testosterone concentrations during treatment.

The compliance with the treatment regimen was high. The participants received 100% of their scheduled GnRH agonist, and 99% of testosterone injections. Serum LH levels were suppressed in all men, demonstrating the effectiveness of GnRH agonist treatment. The treatment regimen was well tolerated. There were no significant changes in PSA or liver enzymes at any dose. However, long-term effects of androgen administration on the prostate, cardiovascular risk, and behavior are unknown.

Table 5. *Change in measures of muscle performance*

| Testosterone Dose | Baseline | Treatment | Change from Baseline | P vs. Zero Change |
|---|--------------|--------------|----------------------|-------------------|
| <i>Leg press strength (kg) (overall ANOVA P = 0.0003)</i> | | | | |

| 600 mg | 26.7 ± 2.7 | 32.5 ± 2.1 | 5.8 ± 2.2 | 0.0265 |

Values are means ± SE.

Serum testosterone levels were measured 7 days after previous injection; they reflect the lowest testosterone levels after an injection. Testosterone concentrations were higher at other time points. Weekly injections of testosterone enanthate are associated with fluctuations in testosterone levels (44). Although nadir testosterone concentrations were highly correlated with testosterone enanthate dose, it is possible that sustained testosterone delivery by a patch or gel might reveal different dose-response relationships, particularly with respect to hemoglobin and HDL cholesterol (19).

There were no significant changes in overall sexual activity or sexual desire in any group, including those receiving the 25-mg dose. Testosterone replacement of hypogonadal men improves frequency of sexual acts and fantasies, sexual desire, and response to visual erotic stimuli (3, 13, 15, 17, 31, 41). Our data demonstrate that serum testosterone concentrations at the lower end of male range can maintain some aspects of sexual function (3, 13). Testosterone has been shown to regulate nitric oxide synthase activity in the cavernosal smooth muscle (32), and it is possible that optimum penile rigidity might require higher testosterone levels than those produced by the 25-mg dose.

This study demonstrates that an increase in circulating testosterone concentrations results in dose-de-

Table 7. Changes in hemoglobin, plasma HDL cholesterol, and PSA

| Testosterone Dose | Baseline | Week 20 | Change from Baseline | P vs. Zero Change |
|--|-------------|-------------|----------------------|-------------------|

Values on each day represent the mean (\pm SE) of all available values on that day. However, the change from baseline represents the difference between paired values only. PSA, prostate-specific antigen; HDL, high-density lipoprotein.

pendent increases in fat-free mass, muscle size, strength, and power. The relationships between circulating testosterone concentrations and changes in fat-free mass and muscle size conform to a single log-linear dose-response curve. Our data do not support the notion of two separate dose-response curves reflecting two independent mechanisms of testosterone action on the muscle. Forbes et al. (22) predicted 25 years ago that the muscle mass accretion during androgen administration is related to the cumulative androgen dose, the product of daily dose and treatment duration. Our data are consistent with Forbes's hypothesis of a linear relationship between testosterone dose and lean mass accretion; however, we do not know whether increasing the treatment duration would lead to further gains in muscle mass.

In addition, we do not know whether responsiveness to testosterone is attenuated in older men. Testosterone dose-response relationships might be modulated by other muscle growth regulators, such as nutritional status, exercise and activity level, glucocorticoids, thyroid hormones, and endogenous growth hormone secretory status.

Serum PSA levels decrease after androgen withdrawal, and testosterone replacement of hypogonadal men increases PSA levels into the normal range (16, 34). We did not find significant changes in PSA at any dose, indicating that the lowest dose of testosterone maintained PSA levels. We did not measure prostate volume in this study; therefore, we do not know whether prostate volume exhibits the same relationship with testosterone dose as PSA levels.

Hemoglobin levels changed significantly in relation to testosterone dose and concentration. Testosterone

regulates erythropoiesis through its effects on erythropoietin and stem cell proliferation (14, 35, 40). Although modest increments in hemoglobin might be beneficial in androgen-deficient men with chronic illness who are anemic, marked increases in hemoglobin levels could increase the risk of cerebrovascular events (25) and hypertension (42).

Although men, on average, perform better on tests of spatial cognition than women, testosterone replacement has not been consistently shown to improve spatial cognition in hypogonadal men (1, 29, 48). We did not find changes in spatial cognition at any dose. The effect size of gender differences in spatial cognition is small; it is possible that our study did not have sufficient power to detect small differences. We cannot exclude the possibility that gender differences in spatial cognition might be due to organizational effects of testosterone and might not respond to changes in testosterone levels in adult men.

Although mean change in fat-free mass and muscle size correlated with testosterone dose and concentration, there was considerable heterogeneity in response to testosterone administration within each group. These individual differences in response to androgen administration might reflect differences in activity level, testosterone metabolism, nutrition, or polymorphisms in androgen receptor, myostatin, 5- α -reductase, or other muscle growth regulators.

Our data demonstrate that different androgen-dependent processes have different testosterone dose-response relationships. Some aspects of sexual function and spatial cognition, and PSA levels, were maintained by relatively low doses of testosterone in GnRH agonist-treated men and did not increase further with administration of higher doses of testosterone. In contrast, graded doses of testosterone were associated with dose and testosterone concentration-dependent changes in fat-free mass, fat mass, muscle volume, leg press strength and power, hemoglobin, IGF-I, and plasma HDL cholesterol. The precise mechanisms for the tissue- and function-specific differences in testosterone dose dependence are not well understood (36). Although only a single androgen receptor protein is expressed in all androgen-responsive tissues, tissue specificity of androgen action might be mediated through combinatorial recruitment of tissue-specific coactivators and corepressors (36).

Testosterone doses associated with significant gains in fat-free mass, muscle size, and strength were associated with significant reductions in plasma HDL concentrations. Further studies are needed to determine whether clinically significant anabolic effects of testosterone can be achieved without adversely affecting cardiovascular risk. Selective androgen receptor modulators that preferentially augment muscle mass and strength, but only minimally affect prostate and cardiovascular risk factors, are desirable (36).

This study was supported primarily by National Institutes of Health (NIH) Grant 1R01-AG-14369; additional support was pro-

vided by Grants 1R01-DK-49296, 1R01-DK-59297-01, Federal Drug Administration Grant ODP 1397, a General Clinical Research Center Grant MO-00425, NIH-National Center for Research Resources-00954, RCMi Grants P20-RR-11145-01 (RCMi Clinical Research Initiative) and G12-RR-03026. BioTechnology General (Iselin, NJ) provided testosterone enanthate, and R. P. Debio (Martigny, Switzerland) provided the GnRH agonist (Decapeptyl).

Foreword

ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) form the specialized system for worldwide standardization. National bodies that are members of ISO or IEC participate in the development of International Standards through technical committees established by the respective organization to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organizations, governmental and non-governmental, in liaison with ISO and IEC, also take part in the work. In the field of conformity assessment, the ISO Committee on conformity assessment (CASCO) is responsible for the development of International Standards and Guides.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

Draft International Standards are circulated to the national bodies for voting. Publication as an International Standard requires approval by at least 75 % of the national bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

ISO/IEC 17025 was prepared by the *ISO Committee on conformity assessment (CASCO)*.

It was circulated for voting to the national bodies of both ISO and IEC, and was approved by both organizations.

This second edition cancels and replaces the first edition (ISO/IEC 17025:1999), which has been technically revised.

Introduction

The first edition (1999) of this International Standard was produced as the result of extensive experience in the implementation of ISO/IEC Guide 25 and EN 45001, both of which it replaced. It contained all of the requirements that testing and calibration laboratories have to meet if they wish to demonstrate that they operate a management system, are technically competent, and are able to generate technically valid results.

The first edition referred to ISO 9001:1994 and ISO 9002:1994. These standards have been superseded by ISO 9001:2000, which made an alignment of ISO/IEC 17025 necessary. In this second edition, clauses have been amended or added only when considered necessary in the light of ISO 9001:2000.

Accreditation bodies that recognize the competence of testing and calibration laboratories should use this International Standard as the basis for their accreditation. Clause 4 specifies the requirements for sound management. Clause 5 specifies the requirements for technical competence for the type of tests and/or calibrations the laboratory undertakes.

Growth in the use of management systems generally has increased the need to ensure that laboratories which form part of larger organizations or offer other services can operate to a quality management system that is seen as compliant with ISO 9001 as well as with this International Standard. Care has been taken, therefore, to incorporate all those requirements of ISO 9001 that are relevant to the scope of testing and calibration services that are covered by the laboratory's management system.

Testing and calibration laboratories that comply with this International Standard will therefore also operate in accordance with ISO 9001.

Conformity of the quality management system within which the laboratory operates to the requirements of ISO 9001 does not of itself demonstrate the competence of the laboratory to produce technically valid data and results. Nor does demonstrated conformity to this International Standard imply conformity of the quality management system within which the laboratory operates to all the requirements of ISO 9001.

The acceptance of testing and calibration results between countries should be facilitated if laboratories comply with this International Standard and if they obtain accreditation from bodies which have entered into mutual recognition agreements with equivalent bodies in other countries using this International Standard.

The use of this International Standard will facilitate cooperation between laboratories and other bodies, and assist in the exchange of information and experience, and in the harmonization of standards and procedures.

General requirements for the competence of testing and calibration laboratories

1 Scope

1.1 This International Standard specifies the general requirements for the competence to carry out tests and/or calibrations, including sampling. It covers testing and calibration performed using standard methods, non-standard methods, and laboratory-developed methods.

1.2 This International Standard is applicable to all organizations performing tests and/or calibrations. These include, for example, first-, second- and third-party laboratories, and laboratories where testing and/or calibration forms part of inspection and product certification.

This International Standard is applicable to all laboratories regardless of the number of personnel or the extent of the scope of testing and/or calibration activities. When a laboratory does not undertake one or more of the activities covered by this International Standard, such as sampling and the design/development of new methods, the requirements of those clauses do not apply.

1.3 The notes given provide clarification of the text, examples and guidance. They do not contain requirements and do not form an integral part of this International Standard.

1.4 This International Standard is for use by laboratories in developing their management system for quality, administrative and technical operations. Laboratory customers, regulatory authorities and accreditation bodies may also use it in confirming or recognizing the competence of laboratories. This International Standard is not intended to be used as the basis for certification of laboratories.

NOTE 1 The term 'management system' in this International Standard means the quality, administrative and technical systems that govern the operations of a laboratory.

NOTE 2 Certification of a management system is sometimes also called registration.

1.5 Compliance with regulatory and safety requirements on the operation of laboratories is not covered by this International Standard.

1.6 If testing and calibration laboratories comply with the requirements of this International Standard, they will operate a quality management system for their testing and calibration activities that also meets the principles of ISO 9001. Annex A provides nominal cross-references between this International Standard and ISO 9001. This International Standard covers technical competence requirements that are not covered by ISO 9001.

NOTE 1 It might be necessary to explain or interpret certain requirements in this International Standard to ensure that the requirements are applied in a consistent manner. Guidance for establishing applications for specific fields, especially for accreditation bodies (see ISO/IEC 17011) is given in Annex B.

NOTE 2 If a laboratory wishes accreditation for part or all of its testing and calibration activities, it should select an accreditation body that operates in accordance with ISO/IEC 17011.

2 Normative references

The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO/IEC 17000, *Conformity assessment — Vocabulary and general principles*

VIM, *International vocabulary of basic and general terms in metrology*, issued by BIPM, IEC, IFCC, ISO, IUPAC, IUPAP and OIML

NOTE Further related standards, guides, etc. on subjects included in this International Standard are given in the Bibliography.

3 Terms and definitions

For the purposes of this document, the relevant terms and definitions given in ISO/IEC 17000 and VIM apply.

NOTE General definitions related to quality are given in ISO 9000, whereas ISO/IEC 17000 gives definitions specifically related to certification and laboratory accreditation. Where different definitions are given in ISO 9000, the definitions in ISO/IEC 17000 and VIM are preferred.

4 Management requirements

4.1 Organization

4.1.1 The laboratory or the organization of which it is part shall be an entity that can be held legally responsible.

4.1.2 It is the responsibility of the laboratory to carry out its testing and calibration activities in such a way as to meet the requirements of this International Standard and to satisfy the needs of the customer, the regulatory authorities or organizations providing recognition.

4.1.3 The management system shall cover work carried out in the laboratory's permanent facilities, at sites away from its permanent facilities, or in associated temporary or mobile facilities.

4.1.4 If the laboratory is part of an organization performing activities other than testing and/or calibration, the responsibilities of key personnel in the organization that have an involvement or influence on the testing and/or calibration activities of the laboratory shall be defined in order to identify potential conflicts of interest.

NOTE 1 Where a laboratory is part of a larger organization, the organizational arrangements should be such that departments having conflicting interests, such as production, commercial marketing or financing do not adversely influence the laboratory's compliance with the requirements of this International Standard.

NOTE 2 If the laboratory wishes to be recognized as a third-party laboratory, it should be able to demonstrate that it is impartial and that it and its personnel are free from any undue commercial, financial and other pressures which might influence their technical judgement. The third-party testing or calibration laboratory should not engage in any activities that may endanger the trust in its independence of judgement and integrity in relation to its testing or calibration activities.

4.1.5 The laboratory shall

- a) have managerial and technical personnel who, irrespective of other responsibilities, have the authority and resources needed to carry out their duties, including the implementation, maintenance and improvement of the management system, and to identify the occurrence of departures from the management system or from the procedures for performing tests and/or calibrations, and to initiate actions to prevent or minimize such departures (see also 5.2);

- b) have arrangements to ensure that its management and personnel are free from any undue internal and external commercial, financial and other pressures and influences that may adversely affect the quality of their work;
- c) have policies and procedures to ensure the protection of its customers' confidential information and proprietary rights, including procedures for protecting the electronic storage and transmission of results;
- d) have policies and procedures to avoid involvement in any activities that would diminish confidence in its competence, impartiality, judgement or operational integrity;
- e) define the organization and management structure of the laboratory, its place in any parent organization, and the relationships between quality management, technical operations and support services;
- f) specify the responsibility, authority and interrelationships of all personnel who manage, perform or verify work affecting the quality of the tests and/or calibrations;
- g) provide adequate supervision of testing and calibration staff, including trainees, by persons familiar with methods and procedures, purpose of each test and/or calibration, and with the assessment of the test or calibration results;
- h) have technical management which has overall responsibility for the technical operations and the provision of the resources needed to ensure the required quality of laboratory operations;
- i) appoint a member of staff as quality manager (however named) who, irrespective of other duties and responsibilities, shall have defined responsibility and authority for ensuring that the management system related to quality is implemented and followed at all times; the quality manager shall have direct access to the highest level of management at which decisions are made on laboratory policy or resources;
- j) appoint deputies for key managerial personnel (see Note);
- k) ensure that its personnel are aware of the relevance and importance of their activities and how they contribute to the achievement of the objectives of the management system.

NOTE Individuals may have more than one function and it may be impractical to appoint deputies for every function.

4.1.6 Top management shall ensure that appropriate communication processes are established within the laboratory and that communication takes place regarding the effectiveness of the management system.

4.2 Management system

4.2.1 The laboratory shall establish, implement and maintain a management system appropriate to the scope of its activities. The laboratory shall document its policies, systems, programmes, procedures and instructions to the extent necessary to assure the quality of the test and/or calibration results. The system's documentation shall be communicated to, understood by, available to, and implemented by the appropriate personnel.

4.2.2 The laboratory's management system policies related to quality, including a quality policy statement, shall be defined in a quality manual (however named). The overall objectives shall be established, and shall be reviewed during management review. The quality policy statement shall be issued under the authority of top management. It shall include at least the following:

- a) the laboratory management's commitment to good professional practice and to the quality of its testing and calibration in servicing its customers;
- b) the management's statement of the laboratory's standard of service;
- c) the purpose of the management system related to quality;

- d) a requirement that all personnel concerned with testing and calibration activities within the laboratory familiarize themselves with the quality documentation and implement the policies and procedures in their work; and
- e) the laboratory management's commitment to comply with this International Standard and to continually improve the effectiveness of the management system.

NOTE The quality policy statement should be concise and may include the requirement that tests and/or calibrations shall always be carried out in accordance with stated methods and customers' requirements. When the test and/or calibration laboratory is part of a larger organization, some quality policy elements may be in other documents.

4.2.3 Top management shall provide evidence of commitment to the development and implementation of the management system and to continually improving its effectiveness.

4.2.4 Top management shall communicate to the organization the importance of meeting customer requirements as well as statutory and regulatory requirements.

4.2.5 The quality manual shall include or make reference to the supporting procedures including technical procedures. It shall outline the structure of the documentation used in the management system.

4.2.6 The roles and responsibilities of technical management and the quality manager, including their responsibility for ensuring compliance with this International Standard, shall be defined in the quality manual.

4.2.7 Top management shall ensure that the integrity of the management system is maintained when changes to the management system are planned and implemented.

4.3 Document control

4.3.1 General

The laboratory shall establish and maintain procedures to control all documents that form part of its management system (internally generated or from external sources), such as regulations, standards, other normative documents, test and/or calibration methods, as well as drawings, software, specifications, instructions and manuals.

NOTE 1 In this context "document" could be policy statements, procedures, specifications, calibration tables, charts, text books, posters, notices, memoranda, software, drawings, plans, etc. These may be on various media, whether hard copy or electronic, and they may be digital, analog, photographic or written.

NOTE 2 The control of data related to testing and calibration is covered in 5.4.7. The control of records is covered in 4.13.

4.3.2 Document approval and issue

4.3.2.1 All documents issued to personnel in the laboratory as part of the management system shall be reviewed and approved for use by authorized personnel prior to issue. A master list or an equivalent document control procedure identifying the current revision status and distribution of documents in the management system shall be established and shall be readily available to preclude the use of invalid and/or obsolete documents.

4.3.2.2 The procedure(s) adopted shall ensure that:

- a) authorized editions of appropriate documents are available at all locations where operations essential to the effective functioning of the laboratory are performed;
- b) documents are periodically reviewed and, where necessary, revised to ensure continuing suitability and compliance with applicable requirements;

- c) invalid or obsolete documents are promptly removed from all points of issue or use, or otherwise assured against unintended use;
- d) obsolete documents retained for either legal or knowledge preservation purposes are suitably marked.

4.3.2.3 Management system documents generated by the laboratory shall be uniquely identified. Such identification shall include the date of issue and/or revision identification, page numbering, the total number of pages or a mark to signify the end of the document, and the issuing authority(ies).

4.3.3 Document changes

4.3.3.1 Changes to documents shall be reviewed and approved by the same function that performed the original review unless specifically designated otherwise. The designated personnel shall have access to pertinent background information upon which to base their review and approval.

4.3.3.2 Where practicable, the altered or new text shall be identified in the document or the appropriate attachments.

4.3.3.3 If the laboratory's document control system allows for the amendment of documents by hand pending the re-issue of the documents, the procedures and authorities for such amendments shall be defined. Amendments shall be clearly marked, initialled and dated. A revised document shall be formally re-issued as soon as practicable.

4.3.3.4 Procedures shall be established to describe how changes in documents maintained in computerized systems are made and controlled.

4.4 Review of requests, tenders and contracts

4.4.1 The laboratory shall establish and maintain procedures for the review of requests, tenders and contracts. The policies and procedures for these reviews leading to a contract for testing and/or calibration shall ensure that:

- a) the requirements, including the methods to be used, are adequately defined, documented and understood (see 5.4.2);
- b) the laboratory has the capability and resources to meet the requirements;
- c) the appropriate test and/or calibration method is selected and is capable of meeting the customers' requirements (see 5.4.2).

Any differences between the request or tender and the contract shall be resolved before any work commences. Each contract shall be acceptable both to the laboratory and the customer.

NOTE 1 The request, tender and contract review should be conducted in a practical and efficient manner, and the effect of financial, legal and time schedule aspects should be taken into account. For internal customers, reviews of requests, tenders and contracts can be performed in a simplified way.

NOTE 2 The review of capability should establish that the laboratory possesses the necessary physical, personnel and information resources, and that the laboratory's personnel have the skills and expertise necessary for the performance of the tests and/or calibrations in question. The review may also encompass results of earlier participation in interlaboratory comparisons or proficiency testing and/or the running of trial test or calibration programmes using samples or items of known value in order to determine uncertainties of measurement, limits of detection, confidence limits, etc.

NOTE 3 A contract may be any written or oral agreement to provide a customer with testing and/or calibration services.

4.4.2 Records of reviews, including any significant changes, shall be maintained. Records shall also be maintained of pertinent discussions with a customer relating to the customer's requirements or the results of the work during the period of execution of the contract.

NOTE For review of routine and other simple tasks, the date and the identification (e.g. the initials) of the person in the laboratory responsible for carrying out the contracted work are considered adequate. For repetitive routine tasks, the review need be made only at the initial enquiry stage or on granting of the contract for on-going routine work performed under a general agreement with the customer, provided that the customer's requirements remain unchanged. For new, complex or advanced testing and/or calibration tasks, a more comprehensive record should be maintained.

4.4.3 The review shall also cover any work that is subcontracted by the laboratory.

4.4.4 The customer shall be informed of any deviation from the contract.

4.4.5 If a contract needs to be amended after work has commenced, the same contract review process shall be repeated and any amendments shall be communicated to all affected personnel.

4.5 Subcontracting of tests and calibrations

4.5.1 When a laboratory subcontracts work, whether because of unforeseen reasons (e.g. workload, need for further expertise or temporary incapacity) or on a continuing basis (e.g. through permanent subcontracting, agency or franchising arrangements), this work shall be placed with a competent subcontractor. A competent subcontractor is one that, for example, complies with this International Standard for the work in question.

4.5.2 The laboratory shall advise the customer of the arrangement in writing and, when appropriate, gain the approval of the customer, preferably in writing.

4.5.3 The laboratory is responsible to the customer for the subcontractor's work, except in the case where the customer or a regulatory authority specifies which subcontractor is to be used.

4.5.4 The laboratory shall maintain a register of all subcontractors that it uses for tests and/or calibrations and a record of the evidence of compliance with this International Standard for the work in question.

4.6 Purchasing services and supplies

4.6.1 The laboratory shall have a policy and procedure(s) for the selection and purchasing of services and supplies it uses that affect the quality of the tests and/or calibrations. Procedures shall exist for the purchase, reception and storage of reagents and laboratory consumable materials relevant for the tests and calibrations.

4.6.2 The laboratory shall ensure that purchased supplies and reagents and consumable materials that affect the quality of tests and/or calibrations are not used until they have been inspected or otherwise verified as complying with standard specifications or requirements defined in the methods for the tests and/or calibrations concerned. These services and supplies used shall comply with specified requirements. Records of actions taken to check compliance shall be maintained.

4.6.3 Purchasing documents for items affecting the quality of laboratory output shall contain data describing the services and supplies ordered. These purchasing documents shall be reviewed and approved for technical content prior to release.

NOTE The description may include type, class, grade, precise identification, specifications, drawings, inspection instructions, other technical data including approval of test results, the quality required and the management system standard under which they were made.

4.6.4 The laboratory shall evaluate suppliers of critical consumables, supplies and services which affect the quality of testing and calibration, and shall maintain records of these evaluations and list those approved.

4.7 Service to the customer

4.7.1 The laboratory shall be willing to cooperate with customers or their representatives in clarifying the customer's request and in monitoring the laboratory's performance in relation to the work performed, provided that the laboratory ensures confidentiality to other customers.

NOTE 1 Such cooperation may include:

- a) providing the customer or the customer's representative reasonable access to relevant areas of the laboratory for the witnessing of tests and/or calibrations performed for the customer;
- b) preparation, packaging, and dispatch of test and/or calibration items needed by the customer for verification purposes.

NOTE 2 Customers value the maintenance of good communication, advice and guidance in technical matters, and opinions and interpretations based on results. Communication with the customer, especially in large assignments, should be maintained throughout the work. The laboratory should inform the customer of any delays or major deviations in the performance of the tests and/or calibrations.

4.7.2 The laboratory shall seek feedback, both positive and negative, from its customers. The feedback shall be used and analysed to improve the management system, testing and calibration activities and customer service.

NOTE Examples of the types of feedback include customer satisfaction surveys and review of test or calibration reports with customers.

4.8 Complaints

The laboratory shall have a policy and procedure for the resolution of complaints received from customers or other parties. Records shall be maintained of all complaints and of the investigations and corrective actions taken by the laboratory (see also 4.11).

4.9 Control of nonconforming testing and/or calibration work

4.9.1 The laboratory shall have a policy and procedures that shall be implemented when any aspect of its testing and/or calibration work, or the results of this work, do not conform to its own procedures or the agreed requirements of the customer. The policy and procedures shall ensure that:

- a) the responsibilities and authorities for the management of nonconforming work are designated and actions (including halting of work and withholding of test reports and calibration certificates, as necessary) are defined and taken when nonconforming work is identified;
- b) an evaluation of the significance of the nonconforming work is made;
- c) correction is taken immediately, together with any decision about the acceptability of the nonconforming work;
- d) where necessary, the customer is notified and work is recalled;
- e) the responsibility for authorizing the resumption of work is defined.

NOTE Identification of nonconforming work or problems with the management system or with testing and/or calibration activities can occur at various places within the management system and technical operations. Examples are customer complaints, quality control, instrument calibration, checking of consumable materials, staff observations or supervision, test report and calibration certificate checking, management reviews and internal or external audits.

4.9.2 Where the evaluation indicates that the nonconforming work could recur or that there is doubt about the compliance of the laboratory's operations with its own policies and procedures, the corrective action procedures given in 4.11 shall be promptly followed.

4.10 Improvement

The laboratory shall continually improve the effectiveness of its management system through the use of the quality policy, quality objectives, audit results, analysis of data, corrective and preventive actions and management review.

4.11 Corrective action

4.11.1 General

The laboratory shall establish a policy and a procedure and shall designate appropriate authorities for implementing corrective action when nonconforming work or departures from the policies and procedures in the management system or technical operations have been identified.

NOTE A problem with the management system or with the technical operations of the laboratory may be identified through a variety of activities, such as control of nonconforming work, internal or external audits, management reviews, feedback from customers and from staff observations.

4.11.2 Cause analysis

The procedure for corrective action shall start with an investigation to determine the root cause(s) of the problem.

NOTE Cause analysis is the key and sometimes the most difficult part in the corrective action procedure. Often the root cause is not obvious and thus a careful analysis of all potential causes of the problem is required. Potential causes could include customer requirements, the samples, sample specifications, methods and procedures, staff skills and training, consumables, or equipment and its calibration.

4.11.3 Selection and implementation of corrective actions

Where corrective action is needed, the laboratory shall identify potential corrective actions. It shall select and implement the action(s) most likely to eliminate the problem and to prevent recurrence.

Corrective actions shall be to a degree appropriate to the magnitude and the risk of the problem.

The laboratory shall document and implement any required changes resulting from corrective action investigations.

4.11.4 Monitoring of corrective actions

The laboratory shall monitor the results to ensure that the corrective actions taken have been effective.

4.11.5 Additional audits

Where the identification of nonconformities or departures casts doubts on the laboratory's compliance with its own policies and procedures, or on its compliance with this International Standard, the laboratory shall ensure that the appropriate areas of activity are audited in accordance with 4.14 as soon as possible.

NOTE Such additional audits often follow the implementation of the corrective actions to confirm their effectiveness. An additional audit should be necessary only when a serious issue or risk to the business is identified.

4.12 Preventive action

4.12.1 Needed improvements and potential sources of nonconformities, either technical or concerning the management system, shall be identified. When improvement opportunities are identified or if preventive action is required, action plans shall be developed, implemented and monitored to reduce the likelihood of the occurrence of such nonconformities and to take advantage of the opportunities for improvement.

4.12.2 Procedures for preventive actions shall include the initiation of such actions and the application of controls to ensure that they are effective.

NOTE 1 Preventive action is a pro-active process to identify opportunities for improvement rather than a reaction to the identification of problems or complaints.

NOTE 2 Apart from the review of the operational procedures, the preventive action might involve analysis of data, including trend and risk analyses and proficiency-testing results.

4.13 Control of records

4.13.1 General

4.13.1.1 The laboratory shall establish and maintain procedures for identification, collection, indexing, access, filing, storage, maintenance and disposal of quality and technical records. Quality records shall include reports from internal audits and management reviews as well as records of corrective and preventive actions.

4.13.1.2 All records shall be legible and shall be stored and retained in such a way that they are readily retrievable in facilities that provide a suitable environment to prevent damage or deterioration and to prevent loss. Retention times of records shall be established.

NOTE Records may be in any media, such as hard copy or electronic media.

4.13.1.3 All records shall be held secure and in confidence.

4.13.1.4 The laboratory shall have procedures to protect and back-up records stored electronically and to prevent unauthorized access to or amendment of these records.

4.13.2 Technical records

4.13.2.1 The laboratory shall retain records of original observations, derived data and sufficient information to establish an audit trail, calibration records, staff records and a copy of each test report or calibration certificate issued, for a defined period. The records for each test or calibration shall contain sufficient information to facilitate, if possible, identification of factors affecting the uncertainty and to enable the test or calibration to be repeated under conditions as close as possible to the original. The records shall include the identity of personnel responsible for the sampling, performance of each test and/or calibration and checking of results.

NOTE 1 In certain fields it may be impossible or impractical to retain records of all original observations.

NOTE 2 Technical records are accumulations of data (see 5.4.7) and information which result from carrying out tests and/or calibrations and which indicate whether specified quality or process parameters are achieved. They may include forms, contracts, work sheets, work books, check sheets, work notes, control graphs, external and internal test reports and calibration certificates, customers' notes, papers and feedback.

4.13.2.2 Observations, data and calculations shall be recorded at the time they are made and shall be identifiable to the specific task.

4.13.2.3 When mistakes occur in records, each mistake shall be crossed out, not erased, made illegible or deleted, and the correct value entered alongside. All such alterations to records shall be signed or initialled by the person making the correction. In the case of records stored electronically, equivalent measures shall be taken to avoid loss or change of original data.

4.14 Internal audits

4.14.1 The laboratory shall periodically, and in accordance with a predetermined schedule and procedure, conduct internal audits of its activities to verify that its operations continue to comply with the requirements of the management system and this International Standard. The internal audit programme shall address all elements of the management system, including the testing and/or calibration activities. It is the responsibility of the quality manager to plan and organize audits as required by the schedule and requested by management. Such audits shall be carried out by trained and qualified personnel who are, wherever resources permit, independent of the activity to be audited.

NOTE The cycle for internal auditing should normally be completed in one year.

4.14.2 When audit findings cast doubt on the effectiveness of the operations or on the correctness or validity of the laboratory's test or calibration results, the laboratory shall take timely corrective action, and shall notify customers in writing if investigations show that the laboratory results may have been affected.

4.14.3 The area of activity audited, the audit findings and corrective actions that arise from them shall be recorded.

4.14.4 Follow-up audit activities shall verify and record the implementation and effectiveness of the corrective action taken.

4.15 Management reviews

4.15.1 In accordance with a predetermined schedule and procedure, the laboratory's top management shall periodically conduct a review of the laboratory's management system and testing and/or calibration activities to ensure their continuing suitability and effectiveness, and to introduce necessary changes or improvements. The review shall take account of:

- the suitability of policies and procedures;
- reports from managerial and supervisory personnel;
- the outcome of recent internal audits;
- corrective and preventive actions;
- assessments by external bodies;
- the results of interlaboratory comparisons or proficiency tests;
- changes in the volume and type of the work;
- customer feedback;
- complaints;
- recommendations for improvement;
- other relevant factors, such as quality control activities, resources and staff training.

NOTE 1 A typical period for conducting a management review is once every 12 months.

NOTE 2 Results should feed into the laboratory planning system and should include the goals, objectives and action plans for the coming year.

NOTE 3 A management review includes consideration of related subjects at regular management meetings.

4.15.2 Findings from management reviews and the actions that arise from them shall be recorded. The management shall ensure that those actions are carried out within an appropriate and agreed timescale.

5 Technical requirements

5.1 General

5.1.1 Many factors determine the correctness and reliability of the tests and/or calibrations performed by a laboratory. These factors include contributions from:

- human factors (5.2);

- accommodation and environmental conditions (5.3);
- test and calibration methods and method validation (5.4);
- equipment (5.5);
- measurement traceability (5.6);
- sampling (5.7);
- the handling of test and calibration items (5.8).

5.1.2 The extent to which the factors contribute to the total uncertainty of measurement differs considerably between (types of) tests and between (types of) calibrations. The laboratory shall take account of these factors in developing test and calibration methods and procedures, in the training and qualification of personnel, and in the selection and calibration of the equipment it uses.

5.2 Personnel

5.2.1 The laboratory management shall ensure the competence of all who operate specific equipment, perform tests and/or calibrations, evaluate results, and sign test reports and calibration certificates. When using staff who are undergoing training, appropriate supervision shall be provided. Personnel performing specific tasks shall be qualified on the basis of appropriate education, training, experience and/or demonstrated skills, as required.

NOTE 1 In some technical areas (e.g. non-destructive testing) it may be required that the personnel performing certain tasks hold personnel certification. The laboratory is responsible for fulfilling specified personnel certification requirements. The requirements for personnel certification might be regulatory, included in the standards for the specific technical field, or required by the customer.

NOTE 2 The personnel responsible for the opinions and interpretation included in test reports should, in addition to the appropriate qualifications, training, experience and satisfactory knowledge of the testing carried out, also have:

- relevant knowledge of the technology used for the manufacturing of the items, materials, products, etc. tested, or the way they are used or intended to be used, and of the defects or degradations which may occur during or in service;
- knowledge of the general requirements expressed in the legislation and standards; and
- an understanding of the significance of deviations found with regard to the normal use of the items, materials, products, etc. concerned.

5.2.2 The management of the laboratory shall formulate the goals with respect to the education, training and skills of the laboratory personnel. The laboratory shall have a policy and procedures for identifying training needs and providing training of personnel. The training programme shall be relevant to the present and anticipated tasks of the laboratory. The effectiveness of the training actions taken shall be evaluated.

5.2.3 The laboratory shall use personnel who are employed by, or under contract to, the laboratory. Where contracted and additional technical and key support personnel are used, the laboratory shall ensure that such personnel are supervised and competent and that they work in accordance with the laboratory's management system.

5.2.4 The laboratory shall maintain current job descriptions for managerial, technical and key support personnel involved in tests and/or calibrations.

NOTE Job descriptions can be defined in many ways. As a minimum, the following should be defined:

- the responsibilities with respect to performing tests and/or calibrations;
- the responsibilities with respect to the planning of tests and/or calibrations and evaluation of results;
- the responsibilities for reporting opinions and interpretations;
- the responsibilities with respect to method modification and development and validation of new methods;

- expertise and experience required;
- qualifications and training programmes;
- managerial duties.

5.2.5 The management shall authorize specific personnel to perform particular types of sampling, test and/or calibration, to issue test reports and calibration certificates, to give opinions and interpretations and to operate particular types of equipment. The laboratory shall maintain records of the relevant authorization(s), competence, educational and professional qualifications, training, skills and experience of all technical personnel, including contracted personnel. This information shall be readily available and shall include the date on which authorization and/or competence is confirmed.

5.3 Accommodation and environmental conditions

5.3.1 Laboratory facilities for testing and/or calibration, including but not limited to energy sources, lighting and environmental conditions, shall be such as to facilitate correct performance of the tests and/or calibrations.

The laboratory shall ensure that the environmental conditions do not invalidate the results or adversely affect the required quality of any measurement. Particular care shall be taken when sampling and tests and/or calibrations are undertaken at sites other than a permanent laboratory facility. The technical requirements for accommodation and environmental conditions that can affect the results of tests and calibrations shall be documented.

5.3.2 The laboratory shall monitor, control and record environmental conditions as required by the relevant specifications, methods and procedures or where they influence the quality of the results. Due attention shall be paid, for example, to biological sterility, dust, electromagnetic disturbances, radiation, humidity, electrical supply, temperature, and sound and vibration levels, as appropriate to the technical activities concerned. Tests and calibrations shall be stopped when the environmental conditions jeopardize the results of the tests and/or calibrations.

5.3.3 There shall be effective separation between neighbouring areas in which there are incompatible activities. Measures shall be taken to prevent cross-contamination.

5.3.4 Access to and use of areas affecting the quality of the tests and/or calibrations shall be controlled. The laboratory shall determine the extent of control based on its particular circumstances.

5.3.5 Measures shall be taken to ensure good housekeeping in the laboratory. Special procedures shall be prepared where necessary.

5.4 Test and calibration methods and method validation

5.4.1 General

The laboratory shall use appropriate methods and procedures for all tests and/or calibrations within its scope. These include sampling, handling, transport, storage and preparation of items to be tested and/or calibrated, and, where appropriate, an estimation of the measurement uncertainty as well as statistical techniques for analysis of test and/or calibration data.

The laboratory shall have instructions on the use and operation of all relevant equipment, and on the handling and preparation of items for testing and/or calibration, or both, where the absence of such instructions could jeopardize the results of tests and/or calibrations. All instructions, standards, manuals and reference data relevant to the work of the laboratory shall be kept up to date and shall be made readily available to personnel (see 4.3). Deviation from test and calibration methods shall occur only if the deviation has been documented, technically justified, authorized, and accepted by the customer.

NOTE International, regional or national standards or other recognized specifications that contain sufficient and concise information on how to perform the tests and/or calibrations do not need to be supplemented or rewritten as internal procedures if these standards are written in a way that they can be used as published by the operating staff in a laboratory. It may be necessary to provide additional documentation for optional steps in the method or additional details.

5.4.2 Selection of methods

The laboratory shall use test and/or calibration methods, including methods for sampling, which meet the needs of the customer and which are appropriate for the tests and/or calibrations it undertakes. Methods published in international, regional or national standards shall preferably be used. The laboratory shall ensure that it uses the latest valid edition of a standard unless it is not appropriate or possible to do so. When necessary, the standard shall be supplemented with additional details to ensure consistent application.

When the customer does not specify the method to be used, the laboratory shall select appropriate methods that have been published either in international, regional or national standards, or by reputable technical organizations, or in relevant scientific texts or journals, or as specified by the manufacturer of the equipment. Laboratory-developed methods or methods adopted by the laboratory may also be used if they are appropriate for the intended use and if they are validated. The customer shall be informed as to the method chosen. The laboratory shall confirm that it can properly operate standard methods before introducing the tests or calibrations. If the standard method changes, the confirmation shall be repeated.

The laboratory shall inform the customer when the method proposed by the customer is considered to be inappropriate or out of date.

5.4.3 Laboratory-developed methods

The introduction of test and calibration methods developed by the laboratory for its own use shall be a planned activity and shall be assigned to qualified personnel equipped with adequate resources.

Plans shall be updated as development proceeds and effective communication amongst all personnel involved shall be ensured.

5.4.4 Non-standard methods

When it is necessary to use methods not covered by standard methods, these shall be subject to agreement with the customer and shall include a clear specification of the customer's requirements and the purpose of the test and/or calibration. The method developed shall have been validated appropriately before use.

NOTE For new test and/or calibration methods, procedures should be developed prior to the tests and/or calibrations being performed and should contain at least the following information:

- a) appropriate identification;
- b) scope;
- c) description of the type of item to be tested or calibrated;
- d) parameters or quantities and ranges to be determined;
- e) apparatus and equipment, including technical performance requirements;
- f) reference standards and reference materials required;
- g) environmental conditions required and any stabilization period needed;
- h) description of the procedure, including
 - affixing of identification marks, handling, transporting, storing and preparation of items,
 - checks to be made before the work is started,
 - checks that the equipment is working properly and, where required, calibration and adjustment of the equipment before each use,
 - the method of recording the observations and results,
 - any safety measures to be observed;
- i) criteria and/or requirements for approval/rejection;
- j) data to be recorded and method of analysis and presentation;
- k) the uncertainty or the procedure for estimating uncertainty.

5.4.5 Validation of methods

5.4.5.1 Validation is the confirmation by examination and the provision of objective evidence that the particular requirements for a specific intended use are fulfilled.

5.4.5.2 The laboratory shall validate non-standard methods, laboratory-designed/developed methods, standard methods used outside their intended scope, and amplifications and modifications of standard methods to confirm that the methods are fit for the intended use. The validation shall be as extensive as is necessary to meet the needs of the given application or field of application. The laboratory shall record the results obtained, the procedure used for the validation, and a statement as to whether the method is fit for the intended use.

NOTE 1 Validation may include procedures for sampling, handling and transportation.

NOTE 2 The techniques used for the determination of the performance of a method should be one of, or a combination of, the following:

- calibration using reference standards or reference materials;
- comparison of results achieved with other methods;
- interlaboratory comparisons;
- systematic assessment of the factors influencing the result;
- assessment of the uncertainty of the results based on scientific understanding of the theoretical principles of the method and practical experience.

NOTE 3 When some changes are made in the validated non-standard methods, the influence of such changes should be documented and, if appropriate, a new validation should be carried out.

5.4.5.3 The range and accuracy of the values obtainable from validated methods (e.g. the uncertainty of the results, detection limit, selectivity of the method, linearity, limit of repeatability and/or reproducibility, robustness against external influences and/or cross-sensitivity against interference from the matrix of the sample/test object), as assessed for the intended use, shall be relevant to the customers' needs.

NOTE 1 Validation includes specification of the requirements, determination of the characteristics of the methods, a check that the requirements can be fulfilled by using the method, and a statement on the validity.

NOTE 2 As method-development proceeds, regular review should be carried out to verify that the needs of the customer are still being fulfilled. Any change in requirements requiring modifications to the development plan should be approved and authorized.

NOTE 3 Validation is always a balance between costs, risks and technical possibilities. There are many cases in which the range and uncertainty of the values (e.g. accuracy, detection limit, selectivity, linearity, repeatability, reproducibility, robustness and cross-sensitivity) can only be given in a simplified way due to lack of information.

5.4.6 Estimation of uncertainty of measurement

5.4.6.1 A calibration laboratory, or a testing laboratory performing its own calibrations, shall have and shall apply a procedure to estimate the uncertainty of measurement for all calibrations and types of calibrations.

5.4.6.2 Testing laboratories shall have and shall apply procedures for estimating uncertainty of measurement. In certain cases the nature of the test method may preclude rigorous, metrologically and statistically valid, calculation of uncertainty of measurement. In these cases the laboratory shall at least attempt to identify all the components of uncertainty and make a reasonable estimation, and shall ensure that the form of reporting of the result does not give a wrong impression of the uncertainty. Reasonable estimation shall be based on knowledge of the performance of the method and on the measurement scope and shall make use of, for example, previous experience and validation data.

NOTE 1 The degree of rigor needed in an estimation of uncertainty of measurement depends on factors such as:

- the requirements of the test method;

- the requirements of the customer;
- the existence of narrow limits on which decisions on conformity to a specification are based.

NOTE 2 In those cases where a well-recognized test method specifies limits to the values of the major sources of uncertainty of measurement and specifies the form of presentation of calculated results, the laboratory is considered to have satisfied this clause by following the test method and reporting instructions (see 5.10).

5.4.6.3 When estimating the uncertainty of measurement, all uncertainty components which are of importance in the given situation shall be taken into account using appropriate methods of analysis.

NOTE 1 Sources contributing to the uncertainty include, but are not necessarily limited to, the reference standards and reference materials used, methods and equipment used, environmental conditions, properties and condition of the item being tested or calibrated, and the operator.

NOTE 2 The predicted long-term behaviour of the tested and/or calibrated item is not normally taken into account when estimating the measurement uncertainty.

NOTE 3 For further information, see ISO 5725 and the Guide to the Expression of Uncertainty in Measurement (see Bibliography).

5.4.7 Control of data

5.4.7.1 Calculations and data transfers shall be subject to appropriate checks in a systematic manner.

5.4.7.2 When computers or automated equipment are used for the acquisition, processing, recording, reporting, storage or retrieval of test or calibration data, the laboratory shall ensure that:

- a) computer software developed by the user is documented in sufficient detail and is suitably validated as being adequate for use;
- b) procedures are established and implemented for protecting the data; such procedures shall include, but not be limited to, integrity and confidentiality of data entry or collection, data storage, data transmission and data processing;
- c) computers and automated equipment are maintained to ensure proper functioning and are provided with the environmental and operating conditions necessary to maintain the integrity of test and calibration data.

NOTE Commercial off-the-shelf software (e.g. wordprocessing, database and statistical programmes) in general use within their designed application range may be considered to be sufficiently validated. However, laboratory software configuration/modifications should be validated as in 5.4.7.2 a).

5.5 Equipment

5.5.1 The laboratory shall be furnished with all items of sampling, measurement and test equipment required for the correct performance of the tests and/or calibrations (including sampling, preparation of test and/or calibration items, processing and analysis of test and/or calibration data). In those cases where the laboratory needs to use equipment outside its permanent control, it shall ensure that the requirements of this International Standard are met.

5.5.2 Equipment and its software used for testing, calibration and sampling shall be capable of achieving the accuracy required and shall comply with specifications relevant to the tests and/or calibrations concerned. Calibration programmes shall be established for key quantities or values of the instruments where these properties have a significant effect on the results. Before being placed into service, equipment (including that used for sampling) shall be calibrated or checked to establish that it meets the laboratory's specification requirements and complies with the relevant standard specifications. It shall be checked and/or calibrated before use (see 5.6).

5.5.3 Equipment shall be operated by authorized personnel. Up-to-date instructions on the use and maintenance of equipment (including any relevant manuals provided by the manufacturer of the equipment) shall be readily available for use by the appropriate laboratory personnel.

5.5.4 Each item of equipment and its software used for testing and calibration and significant to the result shall, when practicable, be uniquely identified.

5.5.5 Records shall be maintained of each item of equipment and its software significant to the tests and/or calibrations performed. The records shall include at least the following:

- a) the identity of the item of equipment and its software;
- b) the manufacturer's name, type identification, and serial number or other unique identification;
- c) checks that equipment complies with the specification (see 5.5.2);
- d) the current location, where appropriate;
- e) the manufacturer's instructions, if available, or reference to their location;
- f) dates, results and copies of reports and certificates of all calibrations, adjustments, acceptance criteria, and the due date of next calibration;
- g) the maintenance plan, where appropriate, and maintenance carried out to date;
- h) any damage, malfunction, modification or repair to the equipment.

5.5.6 The laboratory shall have procedures for safe handling, transport, storage, use and planned maintenance of measuring equipment to ensure proper functioning and in order to prevent contamination or deterioration.

NOTE Additional procedures may be necessary when measuring equipment is used outside the permanent laboratory for tests, calibrations or sampling.

5.5.7 Equipment that has been subjected to overloading or mishandling, gives suspect results, or has been shown to be defective or outside specified limits, shall be taken out of service. It shall be isolated to prevent its use or clearly labelled or marked as being out of service until it has been repaired and shown by calibration or test to perform correctly. The laboratory shall examine the effect of the defect or departure from specified limits on previous tests and/or calibrations and shall institute the "Control of nonconforming work" procedure (see 4.9).

5.5.8 Whenever practicable, all equipment under the control of the laboratory and requiring calibration shall be labelled, coded or otherwise identified to indicate the status of calibration, including the date when last calibrated and the date or expiration criteria when recalibration is due.

5.5.9 When, for whatever reason, equipment goes outside the direct control of the laboratory, the laboratory shall ensure that the function and calibration status of the equipment are checked and shown to be satisfactory before the equipment is returned to service.

5.5.10 When intermediate checks are needed to maintain confidence in the calibration status of the equipment, these checks shall be carried out according to a defined procedure.

5.5.11 Where calibrations give rise to a set of correction factors, the laboratory shall have procedures to ensure that copies (e.g. in computer software) are correctly updated.

5.5.12 Test and calibration equipment, including both hardware and software, shall be safeguarded from adjustments which would invalidate the test and/or calibration results.

5.6 Measurement traceability

5.6.1 General

All equipment used for tests and/or calibrations, including equipment for subsidiary measurements (e.g. for environmental conditions) having a significant effect on the accuracy or validity of the result of the test, calibration or sampling shall be calibrated before being put into service. The laboratory shall have an established programme and procedure for the calibration of its equipment.

NOTE Such a programme should include a system for selecting, using, calibrating, checking, controlling and maintaining measurement standards, reference materials used as measurement standards, and measuring and test equipment used to perform tests and calibrations.

5.6.2 Specific requirements

5.6.2.1 Calibration

5.6.2.1.1 For calibration laboratories, the programme for calibration of equipment shall be designed and operated so as to ensure that calibrations and measurements made by the laboratory are traceable to the International System of Units (SI) (*Système international d'unités*).

A calibration laboratory establishes traceability of its own measurement standards and measuring instruments to the SI by means of an unbroken chain of calibrations or comparisons linking them to relevant primary standards of the SI units of measurement. The link to SI units may be achieved by reference to national measurement standards. National measurement standards may be primary standards, which are primary realizations of the SI units or agreed representations of SI units based on fundamental physical constants, or they may be secondary standards which are standards calibrated by another national metrology institute. When using external calibration services, traceability of measurement shall be assured by the use of calibration services from laboratories that can demonstrate competence, measurement capability and traceability. The calibration certificates issued by these laboratories shall contain the measurement results, including the measurement uncertainty and/or a statement of compliance with an identified metrological specification (see also 5.10.4.2).

NOTE 1 Calibration laboratories fulfilling the requirements of this International Standard are considered to be competent. A calibration certificate bearing an accreditation body logo from a calibration laboratory accredited to this International Standard, for the calibration concerned, is sufficient evidence of traceability of the calibration data reported.

NOTE 2 Traceability to SI units of measurement may be achieved by reference to an appropriate primary standard (see VIM:1993, 6.4) or by reference to a natural constant, the value of which in terms of the relevant SI unit is known and recommended by the General Conference of Weights and Measures (CGPM) and the International Committee for Weights and Measures (CIPM).

NOTE 3 Calibration laboratories that maintain their own primary standard or representation of SI units based on fundamental physical constants can claim traceability to the SI system only after these standards have been compared, directly or indirectly, with other similar standards of a national metrology institute.

NOTE 4 The term "identified metrological specification" means that it must be clear from the calibration certificate which specification the measurements have been compared with, by including the specification or by giving an unambiguous reference to the specification.

NOTE 5 When the terms "international standard" or "national standard" are used in connection with traceability, it is assumed that these standards fulfil the properties of primary standards for the realization of SI units.

NOTE 6 Traceability to national measurement standards does not necessarily require the use of the national metrology institute of the country in which the laboratory is located.

NOTE 7 If a calibration laboratory wishes or needs to obtain traceability from a national metrology institute other than in its own country, this laboratory should select a national metrology institute that actively participates in the activities of BIPM either directly or through regional groups.

NOTE 8 The unbroken chain of calibrations or comparisons may be achieved in several steps carried out by different laboratories that can demonstrate traceability.

5.6.2.1.2 There are certain calibrations that currently cannot be strictly made in SI units. In these cases calibration shall provide confidence in measurements by establishing traceability to appropriate measurement standards such as:

- the use of certified reference materials provided by a competent supplier to give a reliable physical or chemical characterization of a material;
- the use of specified methods and/or consensus standards that are clearly described and agreed by all parties concerned.

Participation in a suitable programme of interlaboratory comparisons is required where possible.

5.6.2.2 Testing

5.6.2.2.1 For testing laboratories, the requirements given in 5.6.2.1 apply for measuring and test equipment with measuring functions used, unless it has been established that the associated contribution from the calibration contributes little to the total uncertainty of the test result. When this situation arises, the laboratory shall ensure that the equipment used can provide the uncertainty of measurement needed.

NOTE The extent to which the requirements in 5.6.2.1 should be followed depends on the relative contribution of the calibration uncertainty to the total uncertainty. If calibration is the dominant factor, the requirements should be strictly followed.

5.6.2.2.2 Where traceability of measurements to SI units is not possible and/or not relevant, the same requirements for traceability to, for example, certified reference materials, agreed methods and/or consensus standards, are required as for calibration laboratories (see 5.6.2.1.2).

5.6.3 Reference standards and reference materials

5.6.3.1 Reference standards

The laboratory shall have a programme and procedure for the calibration of its reference standards. Reference standards shall be calibrated by a body that can provide traceability as described in 5.6.2.1. Such reference standards of measurement held by the laboratory shall be used for calibration only and for no other purpose, unless it can be shown that their performance as reference standards would not be invalidated. Reference standards shall be calibrated before and after any adjustment.

5.6.3.2 Reference materials

Reference materials shall, where possible, be traceable to SI units of measurement, or to certified reference materials. Internal reference materials shall be checked as far as is technically and economically practicable.

5.6.3.3 Intermediate checks

Checks needed to maintain confidence in the calibration status of reference, primary, transfer or working standards and reference materials shall be carried out according to defined procedures and schedules.

5.6.3.4 Transport and storage

The laboratory shall have procedures for safe handling, transport, storage and use of reference standards and reference materials in order to prevent contamination or deterioration and in order to protect their integrity.

NOTE Additional procedures may be necessary when reference standards and reference materials are used outside the permanent laboratory for tests, calibrations or sampling.

5.7 Sampling

5.7.1 The laboratory shall have a sampling plan and procedures for sampling when it carries out sampling of substances, materials or products for subsequent testing or calibration. The sampling plan as well as the sampling procedure shall be available at the location where sampling is undertaken. Sampling plans shall, whenever reasonable, be based on appropriate statistical methods. The sampling process shall address the factors to be controlled to ensure the validity of the test and calibration results.

NOTE 1 Sampling is a defined procedure whereby a part of a substance, material or product is taken to provide for testing or calibration of a representative sample of the whole. Sampling may also be required by the appropriate specification for which the substance, material or product is to be tested or calibrated. In certain cases (e.g. forensic analysis), the sample may not be representative but is determined by availability.

NOTE 2 Sampling procedures should describe the selection, sampling plan, withdrawal and preparation of a sample or samples from a substance, material or product to yield the required information.

5.7.2 Where the customer requires deviations, additions or exclusions from the documented sampling procedure, these shall be recorded in detail with the appropriate sampling data and shall be included in all documents containing test and/or calibration results, and shall be communicated to the appropriate personnel.

5.7.3 The laboratory shall have procedures for recording relevant data and operations relating to sampling that forms part of the testing or calibration that is undertaken. These records shall include the sampling procedure used, the identification of the sampler, environmental conditions (if relevant) and diagrams or other equivalent means to identify the sampling location as necessary and, if appropriate, the statistics the sampling procedures are based upon.

5.8 Handling of test and calibration items

5.8.1 The laboratory shall have procedures for the transportation, receipt, handling, protection, storage, retention and/or disposal of test and/or calibration items, including all provisions necessary to protect the integrity of the test or calibration item, and to protect the interests of the laboratory and the customer.

5.8.2 The laboratory shall have a system for identifying test and/or calibration items. The identification shall be retained throughout the life of the item in the laboratory. The system shall be designed and operated so as to ensure that items cannot be confused physically or when referred to in records or other documents. The system shall, if appropriate, accommodate a sub-division of groups of items and the transfer of items within and from the laboratory.

5.8.3 Upon receipt of the test or calibration item, abnormalities or departures from normal or specified conditions, as described in the test or calibration method, shall be recorded. When there is doubt as to the suitability of an item for test or calibration, or when an item does not conform to the description provided, or the test or calibration required is not specified in sufficient detail, the laboratory shall consult the customer for further instructions before proceeding and shall record the discussion.

5.8.4 The laboratory shall have procedures and appropriate facilities for avoiding deterioration, loss or damage to the test or calibration item during storage, handling and preparation. Handling instructions provided with the item shall be followed. When items have to be stored or conditioned under specified environmental conditions, these conditions shall be maintained, monitored and recorded. Where a test or calibration item or a portion of an item is to be held secure, the laboratory shall have arrangements for storage and security that protect the condition and integrity of the secured items or portions concerned.

NOTE 1 Where test items are to be returned into service after testing, special care is required to ensure that they are not damaged or injured during the handling, testing or storing/waiting processes.

NOTE 2 A sampling procedure and information on storage and transport of samples, including information on sampling factors influencing the test or calibration result, should be provided to those responsible for taking and transporting the samples.

NOTE 3 Reasons for keeping a test or calibration item secure can be for reasons of record, safety or value, or to enable complementary tests and/or calibrations to be performed later.

5.9 Assuring the quality of test and calibration results

5.9.1 The laboratory shall have quality control procedures for monitoring the validity of tests and calibrations undertaken. The resulting data shall be recorded in such a way that trends are detectable and, where practicable, statistical techniques shall be applied to the reviewing of the results. This monitoring shall be planned and reviewed and may include, but not be limited to, the following:

- a) regular use of certified reference materials and/or internal quality control using secondary reference materials;
- b) participation in interlaboratory comparison or proficiency-testing programmes;
- c) replicate tests or calibrations using the same or different methods;
- d) retesting or recalibration of retained items;
- e) correlation of results for different characteristics of an item.

NOTE The selected methods should be appropriate for the type and volume of the work undertaken.

5.9.2 Quality control data shall be analysed and, where they are found to be outside pre-defined criteria, planned action shall be taken to correct the problem and to prevent incorrect results from being reported.

5.10 Reporting the results

5.10.1 General

The results of each test, calibration, or series of tests or calibrations carried out by the laboratory shall be reported accurately, clearly, unambiguously and objectively, and in accordance with any specific instructions in the test or calibration methods.

The results shall be reported, usually in a test report or a calibration certificate (see Note 1), and shall include all the information requested by the customer and necessary for the interpretation of the test or calibration results and all information required by the method used. This information is normally that required by 5.10.2, and 5.10.3 or 5.10.4.

In the case of tests or calibrations performed for internal customers, or in the case of a written agreement with the customer, the results may be reported in a simplified way. Any information listed in 5.10.2 to 5.10.4 which is not reported to the customer shall be readily available in the laboratory which carried out the tests and/or calibrations.

NOTE 1 Test reports and calibration certificates are sometimes called test certificates and calibration reports, respectively.

NOTE 2 The test reports or calibration certificates may be issued as hard copy or by electronic data transfer provided that the requirements of this International Standard are met.

5.10.2 Test reports and calibration certificates

Each test report or calibration certificate shall include at least the following information, unless the laboratory has valid reasons for not doing so:

- a) a title (e.g. "Test Report" or "Calibration Certificate");
- b) the name and address of the laboratory, and the location where the tests and/or calibrations were carried out, if different from the address of the laboratory;

- c) unique identification of the test report or calibration certificate (such as the serial number), and on each page an identification in order to ensure that the page is recognized as a part of the test report or calibration certificate, and a clear identification of the end of the test report or calibration certificate;
- d) the name and address of the customer;
- e) identification of the method used;
- f) a description of, the condition of, and unambiguous identification of the item(s) tested or calibrated;
- g) the date of receipt of the test or calibration item(s) where this is critical to the validity and application of the results, and the date(s) of performance of the test or calibration;
- h) reference to the sampling plan and procedures used by the laboratory or other bodies where these are relevant to the validity or application of the results;
- i) the test or calibration results with, where appropriate, the units of measurement;
- j) the name(s), function(s) and signature(s) or equivalent identification of person(s) authorizing the test report or calibration certificate;
- k) where relevant, a statement to the effect that the results relate only to the items tested or calibrated.

NOTE 1 Hard copies of test reports and calibration certificates should also include the page number and total number of pages.

NOTE 2 It is recommended that laboratories include a statement specifying that the test report or calibration certificate shall not be reproduced except in full, without written approval of the laboratory.

5.10.3 Test reports

5.10.3.1 In addition to the requirements listed in 5.10.2, test reports shall, where necessary for the interpretation of the test results, include the following:

- a) deviations from, additions to, or exclusions from the test method, and information on specific test conditions, such as environmental conditions;
- b) where relevant, a statement of compliance/non-compliance with requirements and/or specifications;
- c) where applicable, a statement on the estimated uncertainty of measurement; information on uncertainty is needed in test reports when it is relevant to the validity or application of the test results, when a customer's instruction so requires, or when the uncertainty affects compliance to a specification limit;
- d) where appropriate and needed, opinions and interpretations (see 5.10.5);
- e) additional information which may be required by specific methods, customers or groups of customers.

5.10.3.2 In addition to the requirements listed in 5.10.2 and 5.10.3.1, test reports containing the results of sampling shall include the following, where necessary for the interpretation of test results:

- a) the date of sampling;
- b) unambiguous identification of the substance, material or product sampled (including the name of the manufacturer, the model or type of designation and serial numbers as appropriate);
- c) the location of sampling, including any diagrams, sketches or photographs;
- d) a reference to the sampling plan and procedures used;

- e) details of any environmental conditions during sampling that may affect the interpretation of the test results;
- f) any standard or other specification for the sampling method or procedure, and deviations, additions to or exclusions from the specification concerned.

5.10.4 Calibration certificates

5.10.4.1 In addition to the requirements listed in 5.10.2, calibration certificates shall include the following, where necessary for the interpretation of calibration results:

- a) the conditions (e.g. environmental) under which the calibrations were made that have an influence on the measurement results;
- b) the uncertainty of measurement and/or a statement of compliance with an identified metrological specification or clauses thereof;
- c) evidence that the measurements are traceable (see Note 2 in 5.6.2.1.1).

5.10.4.2 The calibration certificate shall relate only to quantities and the results of functional tests. If a statement of compliance with a specification is made, this shall identify which clauses of the specification are met or not met.

When a statement of compliance with a specification is made omitting the measurement results and associated uncertainties, the laboratory shall record those results and maintain them for possible future reference.

When statements of compliance are made, the uncertainty of measurement shall be taken into account.

5.10.4.3 When an instrument for calibration has been adjusted or repaired, the calibration results before and after adjustment or repair, if available, shall be reported.

5.10.4.4 A calibration certificate (or calibration label) shall not contain any recommendation on the calibration interval except where this has been agreed with the customer. This requirement may be superseded by legal regulations.

5.10.5 Opinions and interpretations

When opinions and interpretations are included, the laboratory shall document the basis upon which the opinions and interpretations have been made. Opinions and interpretations shall be clearly marked as such in a test report.

NOTE 1 Opinions and interpretations should not be confused with inspections and product certifications as intended in ISO/IEC 17020 and ISO/IEC Guide 65.

NOTE 2 Opinions and interpretations included in a test report may comprise, but not be limited to, the following:

- an opinion on the statement of compliance/noncompliance of the results with requirements;
- fulfilment of contractual requirements;
- recommendations on how to use the results;
- guidance to be used for improvements.

NOTE 3 In many cases it might be appropriate to communicate the opinions and interpretations by direct dialogue with the customer. Such dialogue should be written down.

5.10.6 Testing and calibration results obtained from subcontractors

When the test report contains results of tests performed by subcontractors, these results shall be clearly identified. The subcontractor shall report the results in writing or electronically.

When a calibration has been subcontracted, the laboratory performing the work shall issue the calibration certificate to the contracting laboratory.

5.10.7 Electronic transmission of results

In the case of transmission of test or calibration results by telephone, telex, facsimile or other electronic or electromagnetic means, the requirements of this International Standard shall be met (see also 5.4.7).

5.10.8 Format of reports and certificates

The format shall be designed to accommodate each type of test or calibration carried out and to minimize the possibility of misunderstanding or misuse.

NOTE 1 Attention should be given to the lay-out of the test report or calibration certificate, especially with regard to the presentation of the test or calibration data and ease of assimilation by the reader.

NOTE 2 The headings should be standardized as far as possible.

5.10.9 Amendments to test reports and calibration certificates

Material amendments to a test report or calibration certificate after issue shall be made only in the form of a further document, or data transfer, which includes the statement:

"Supplement to Test Report [or Calibration Certificate], serial number... [or as otherwise identified]",

or an equivalent form of wording.

Such amendments shall meet all the requirements of this International Standard.

When it is necessary to issue a complete new test report or calibration certificate, this shall be uniquely identified and shall contain a reference to the original that it replaces.

ISO/IEC 17025 covers several technical competence requirements that are not covered by ISO 9001:2000.

Annex B

(informative)

Guidelines for establishing applications for specific fields

B.1 The requirements specified in this International Standard are stated in general terms and, while they are applicable to all test and calibration laboratories, explanations might be needed. Such explanations on applications are herein referred to as applications. Applications should not include additional general requirements not included in this International Standard.

B.2 Applications can be thought of as an elaboration of the generally stated criteria (requirements) of this International Standard for specified fields of test and calibration, test technologies, products, materials or specific tests or calibrations. Accordingly, applications should be established by persons having appropriate technical knowledge and experience, and should address items that are essential or most important for the proper conduct of a test or calibration.

B.3 Depending on the application at hand, it may be necessary to establish applications for the technical requirements of this International Standard. Establishing applications may be accomplished by simply providing detail or adding extra information to the already generally stated requirements in each of the clauses (e.g. specific limitations to the temperature and humidity in the laboratory).

In some cases the applications will be quite limited, applying only to a given test or calibration method or to a group of calibration or test methods. In other cases the applications may be quite broad, applying to the testing or calibration of various products or items or to entire fields of testing or calibration.

B.4 If the applications apply to a group of test or calibration methods in an entire technical field, common wording should be used for all of the methods.

Alternatively, it may be necessary to develop a separate document of applications to supplement this International Standard for specific types or groups of tests or calibrations, products, materials or technical fields of tests or calibrations. Such a document should provide only the necessary supplementary information, while maintaining this International Standard as the governing document through reference. Applications which are too specific should be avoided in order to limit the proliferation of detailed documents.

B.5 The guidance in this annex should be used by accreditation bodies and other types of evaluation bodies when they develop applications for their own purposes (e.g. accreditation in specific areas).

Landis pris au piège

Selon L'Equipe, les analyses rétroactives effectuées sur sept échantillons de Floyd Landis démontrent bien la présence de testostérone exogène. L'Américain encourt deux ans de suspension.

Par Florian Egly

Des résultats accablants

Cette fois-ci, Floyd Landis ne pourra pas se retrancher derrière une prétendue production naturelle exceptionnellement élevée de testostérone ni se dérober en dénonçant la supposée incompétence du Laboratoire de Châtenay-Malabry (LNDD). Les deux lignes de défense avancées par le coureur américain depuis son contrôle positif sur le Tour de France sont ainsi tombées à plat. Selon une information de L'Equipe, sept échantillons appartenant à l'ancien Maillot Jaune et conservés depuis la Grande Boucle 2006 ont dévoilé la présence de testostérone exogène, lors d'analyses rétroactives réalisées la semaine dernière par le LNDD. Ces nouvelles pratiques avaient été commandées par l'USADA, l'Agence Américaine Antidopage, chargée du dossier Landis, sur la base d'une nouvelle technique plus fiable (l'IRMS), capable de différencier le taux de testostérone endogène d'une aide extérieure. Deux experts de l'agence, de même que deux représentants du coureur, ont assisté à ces analyses, ce qui révoque donc l'argument d'une soi-disant manipulation de la part du laboratoire français..

Pas une surprise

La surprise n'est pas immense. Ces révélations ne font que confirmer le contrôle positif de l'Américain au soir de sa «fantastique» chevauchée vers Morzine, le 20 juillet, et qui avait été conforté après examen de l'échantillon B quelques semaines plus tard. Seulement, Landis avait réussi jusqu'ici à s'en sortir par plusieurs pirouettes, multipliant tous les recours possibles et bénéficiant surtout de deux bourdes de procédure du Laboratoire de Châtenay-Malabry : une erreur d'étiquetage sur le procès-verbal de la contre-expertise et la présence de deux mêmes agents lors des contrôles des échantillons A et B, ce qui est interdit par le règlement. Convoqué par l'AFLD, l'Agence Française de Lutte contre le Dopage, en février dernier, l'ex-leader de Phonak avait négocié un report en acceptant de ne pas prendre le départ du Tour 2007, l'autorisant ainsi à se confronter en premier lieu à l'USADA, qu'il jugeait plus compétente. Avant de recevoir Floyd Landis le 14 mai prochain, celle-ci avait pris une mesure inédite fin mars en convoquant donc des analyses rétroactives sur des échantillons qui s'étaient révélés négatifs à l'époque, la méthode d'analyse n'étant pas aussi précise : lesquels seraient donc bien positifs à la testostérone.

Landis crie au scandale

Evidemment, celui qui est encore vainqueur du Tour de France 2006 à ce jour n'a pas tardé à réagir, criant une nouvelle fois au complot. L'Américain reproche notamment à l'USADA d'avoir empêché à l'un de ses consultants l'accès au LNDD. «Comment puis-je prouver mon innocence alors que l'USADA ne cesse de violer ses propres règles ? Je suis ulcéré par le comportement de l'USADA et du LNDD. Ensemble, ils ont transformé cette procédure en une attaque en règle contre mes droits civils et en une parodie de justice», lance-t-il notamment dans un communiqué publié sur son site internet. La balle est désormais dans le camp de l'Agence Américaine Antidopage, seule habilitée à sanctionner Floyd Landis. Convoqué le 14 mai par l'USADA, il risque une suspension de deux ans et pourrait être le deuxième vainqueur du Tour de France de l'histoire, après Maurice Garin en 1904, à être déchu de son titre, le premier pour dopage.

Landis caught in the trap
4/23/07

According to l'Equipe, the retroactive analyses of seven Floyd Landis specimens clearly show the presence of exogenous testosterone. The American is facing a two-year suspension.

By Florian Egly

Crushing results

This time, Floyd Landis will not be able to hide behind a supposed exceptionally elevated natural testosterone production, nor steal away by denouncing the supposed incompetence of the laboratory at Châtenay-Malabry (LNDD). These two lines of defense put forward by the American racer since his positive test result during the Tour de France have fallen flat. According to a report in l'Equipe, seven specimens belonging to the former Yellow Jersey and preserved since the 2006 Grande Boucle have revealed the presence of exogenous testosterone, during retroactive analyses performed this last week by the LNDD. The new tests--based on the more reliable new IRMS technique (which can distinguish the level of endogenous testosterone from that due to external sources)--had been requested by the USADA, which is in charge of the Landis case. Two experts from the agency, along with two of the rider's representatives, witnessed these analyses, which thus rebuts the argument of any so-called manipulation on the part of the French laboratory.

No surprise

This is no big surprise. The revelations only confirm the American's positive test the evening of his 'fantastic' gallop to Morzine, July 20, which itself had been confirmed after analysis of that test's B sample several weeks later. Up until now, though, Landis had been able to get out of it by several maneuvers, using every recourse available, and benefiting especially from two procedural blunders by the lab at Châtenay-Malabry: a labeling error in the summary of the confirming test, and the presence of two technicians on the testing of both the A and B samples, which is prohibited by rule. Summoned by the AFLD last February, the former Phonak leader negotiated a postponement by accepting not to be at the start of the

2007 Tour de France. This allowed him to confront the USADA, which he considered more competent, first. Before meeting with Floyd Landis on next May 14, the USADA took the unprecedented step at the end of March of requiring retroactive analyses of the specimens which had tested negative at the time they were taken, the method of analysis used not being as precise.

It is these specimens that indeed seem to be positive for testosterone.

Landis cries foul

Obviously, the man who is today still the winner of the 2006 Tour de France did not waste time before reacting, once again denouncing a conspiracy. The American notably reproaches the USADA for having denied one of his consultants access to the LNDD. "How can I prove my innocence when the USADA won't stop violating its own rules? I am torn up by the behavior of the USADA and the LNDD. Together, they have transformed this process into an attack on my civil rights and a parody of justice," he asserts in a press release published on his internet site. The ball is now in the USADA's court, the only agency authorized to sanction Floyd Landis. Summoned by the USADA for May 14, he risks a suspension of two years and could be the first winner in the history of the Tour de France to be stripped of his title.

CYCLISME

DOPAGE

Landis archi-positif !

Les analyses rétrospectives sont claires : l'Américain était plusieurs fois positif à la testostérone sur le Tour 2006.

Il n'y a désormais plus aucun doute : Floyd Landis a bel et bien triché pour remporter le Tour de France 2006. Contrôlé positif à l'issue de

la 17 étape, l'Américain

a depuis toujours nié

s'être dopé en espérant échapper à toute sanction pour vice

de procédure. Mais les analyses rétroactives

de sept échantillons urinaires prélevés pendant la Grande Boucle ont confirmé

une prise exogène

de testostérone.

CONTRÔLÉ POSITIF à la testostérone une première fois, à l'issue de la 17 étape du dernier Tour de France, Floyd Landis, vainqueur en sursis, va devoir désormais réorienter sérieusement sa stratégie de défense. En effet, ce n'est pas une, mais plusieurs infractions aux règles antidopage que le trentenaire américain a commises en juillet 2006, puisque plusieurs de ses échantillons prélevés lors de cette même épreuve contiennent des traces de testostérone synthétique.

Après s'être opposé vigoureusement à l'idée même d'analyses complémentaires menées par le laboratoire de Châtenay-Malabry (LNDD), l'ancien leader de Phonak avait dû finalement se résoudre à cette extrémité, en vertu d'une décision prononcée par le panel (AAA) de l'Agence américaine antidopage (USADA). On comprend désormais mieux son appréhension depuis que l'on connaît le résultat des analyses supplémentaires, lesquelles ont duré une semaine en raison de la complexité de la méthode utilisée, la spectrométrie de masse (IRMS, voir ci-dessous).

Cette méthodologie, qui permet de distinguer la présence de testostérone naturelle fabriquée par l'organisme de celle produite par synthèse, livre en effet des résultats irréfutables et n'aboutit jamais à la mise en cause de faux positifs. Parmi les sept échantillons restants, analysés une nouvelle fois, plusieurs sont positifs.

Comment dès lors expliquer que des échantillons déclarés négatifs dans un premier temps puissent être déclarés positifs après de nouvelles analyses ? Tout simplement parce que, dans le cadre de la détection de routine de la testostérone, les laboratoires débutent le processus de l'analyse par l'établissement du célèbre ratio testostérone sur épitestostérone (T/E). Ce n'est que lorsque celui-ci est supérieur à 4, en vertu des règles édictées par l'Agence mondiale antidopage, que les laboratoires commencent alors une instruction plus poussée, laquelle passe, lorsqu'ils sont équipés du matériel adéquat, par l'utilisation de la méthode IRMS. Lors du Tour de France 2006, un seul des échantillons appartenant à Landis dépassait la barre fatidique des 4 (11, en l'occurrence, comme seuil de confirmation). Les sept autres échantillons prélevés sur l'Américain étaient en revanche en deçà du seuil d'instruction et n'ont pas fait l'objet de recherche par IRMS.. C'est cette nouvelle opération analytique qui a été menée à Châtenay-Malabry ces derniers jours.

Les droits

de la défense

respectés

Landis pourra-t-il, dès lors, comme il ne cesse de le faire depuis l'annonce de son premier contrôle positif, remettre en cause la crédibilité et la compétence des techniciens du LNDD, lui qui avait demandé, après s'être résigné au verdict du panel, que ces fameuses analyses rétrospectives soient effectuées au sein du laboratoire de Los Angeles (UCLA) ? Difficile.

En effet, les analyses supplémentaires opérées en France ont été menées dans le cadre de règles strictes, en aveugle (avec de nouveaux codes), avec l'adjonction d'échantillons supplémentaires (des leurres destinés à rendre toute identification aléatoire) et en présence de plusieurs experts représentant les deux parties, l'USADA et Landis (voir ci-dessous). Cette dernière précaution, imposée par l'Agence française de lutte contre le dopage (AFLD), s'est révélée extrêmement judicieuse pour préserver l'aspect contradictoire de l'expertise, et le coureur et sa cohorte d'avocats auront bien du mal à remettre en cause un processus qu'ils ont pu observer de très près. Nul doute en effet que les deux personnes présentes à Châtenay-Malabry durant les sept jours d'analyses un avocat et un scientifique auraient stoppé le processus ou crié au scandale si une irrégularité s'était produite au sein du laboratoire.

Bien entendu, ils ne devraient néanmoins pas renoncer à stigmatiser telle ou telle insuffisance, mais l'USADA, dont les deux représentants ont quitté la France dès samedi soir dernier, ont semblé totalement satisfaits par la manière dont les opérations se sont déroulées.

Désormais, et alors que cette même agence américaine s'intéresse également au financement de la campagne de défense de Landis, on attend avec curiosité la tonalité que ce dernier adoptera le 14 mai à Los Angeles, jour de sa comparution devant le panel de l'USADA.

Les débats, qui à l'heure actuelle sont évalués à une dizaine de jours, seront-ils publics, comme Landis l'avait expressément demandé ? Ce dernier, face à la nouvelle consistance des accusations, se raviserait-il et opterait-il plutôt pour une négociation intelligente ? La seule certitude, pour l'heure, c'est que l'Américain, qui s'est engagé auprès des instances françaises ad hoc (AFLD) à ne pas courir en France en 2007, pourrait également s'abstenir en 2008. Suspension oblige.

Doping: Landis overwhelmed
by Damien Ressirot
L'Equipe
4/23/07

Supplementary analyses just completed on seven Floyd Landis specimens taken during the 2006 Tour de France and originally classified as negative, have on several occasions made it possible to reveal clear traces of synthetic testosterone. The American rider, winner of the Grande Boucle but officially testing positive for a first time at the conclusion of the race (also for synthetic testosterone), must appear before an ADA panel this coming May 14 and risks a two year suspension.

After initial opposition to the retroactive analyses, Landis, confronted now with these new crushing results from the laboratory at Châtenay-Malabry (LNDD), is now going to have to readjust his defense strategy as quickly as possible. For these new positive specimens--revealed by means of the IRMS technique (which distinguishes the origin of any testosterone detected as natural or synthetic)--will support the current accusation made by the USADA (and the UCI). Moreover, Floyd Landis, who has for several months been making an effort to discredit the French laboratory, will have a great deal of trouble using that argument this time: the latest analyses, performed during this past week and completed this weekend, were carried out in the presence of two experts named by the rider and two representatives of the USADA.

Piratage à Châtenay-Malabry

Le Laboratoire national de dépistage du dopage a été victime de plusieurs intrusions dans son système informatique.

LE MONDE DE LA LUTTE antidopage est vertigineux. Ceux qui doutent encore de la vérité de ce postulat seront attentifs au dernier thriller dans lequel se trouve plongé le Laboratoire national de dépistage du dopage de Châtenay-Malabry (LNDD), victime de pirates qui se sont introduits dans les systèmes informatiques internes.

Une plainte officielle a été déposée mardi dernier par Pierre Bordry, président de l'Agence française de lutte contre le dopage (AFLD), tutelle officielle du laboratoire depuis le 1 octobre. L'enquête a été confiée aux policiers de l'Office central de lutte contre la criminalité liée aux technologies de l'information et de la communication (OCLCTIC), qui sont entrés immédiatement en action. Car l'enjeu est de taille.

Outre le délit en lui-même, les informations contenues dans le système du laboratoire français accrédité sont en effet très sensibles et concernent des dossiers de dopage explosifs, dont les plus récents, médiatiquement parlant, sont relatifs à deux cyclistes américains, Lance Armstrong (*) et Floyd Landis, contrôlé positif à la testostérone lors du dernier Tour de France.

Qu'en pense Landis ?

Les enquêteurs de l'OCLCTIC ont donc entendu en toute hâte plusieurs membres du laboratoire, dont son directeur, le P Jacques De Ceaurriz. Leur enquête vise à identifier les auteurs de cette violation et le mobile de ce délit.

Pour ce faire, les policiers disposent d'éléments assez précis, essentiellement constitués de courriels et de courriers qui ont été distribués à différentes personnes, institutions sportives et médias.

Ces envois, tout au moins pour ceux qui concernent la France, sont constitués chacun d'une lettre de présentation datée de la première quinzaine de septembre, rédigée dans un français assez approximatif et émanant à première vue d'un Anglo-Saxon. Ces quelques lignes ont pour but d'avertir leur lecteur que les informations contenues dans les pièces jointes à cette lettre sont « très intéressantes » et se veulent révélatrices de la propension du laboratoire français à commettre des erreurs dans ses analyses.

Comment les auteurs de cette manipulation s'y sont-ils pris pour arriver, très

péniblement, à dénoncer l'incompétence supposée du LNDD ? En utilisant tout simplement quelques passages parmi les documents internes au laboratoire relatifs à des rectifications antérieures de résultats d'analyse et en les remettant en scène de manière totalement artificielle, hors de leur contexte initial. Une lecture attentive de ces pièces confirme d'ailleurs leur falsification. Les courriers ont été reconstitués. Dépourvus d'en-tête officiel du LNDD, ces documents ont dû être remis en forme par le ou les faussaires, lesquels ont rajouté des en-têtes comportant des erreurs ! Ainsi, le logo du LNDD comporte une adresse sise à « Châtenay-Malabry ».

Ces courriers ou courriels, semblables pour la plupart, ont été transmis au Comité olympique international (CIO), à l'Agence mondiale antidopage (AMA), à l'Union cycliste internationale (UCI), à Howard Jacobs, avocat américain de Floyd Landis, à différents journalistes et à certains laboratoires antidopage étrangers accrédités par l'AMA. Celui de Montréal, dirigé par le D Christiane Ayotte, a bien reçu un courriel de ce type, fin octobre, et a rapidement donné l'alerte. Jointe hier au téléphone, cette dernière nous a raconté sa stupéfaction : « J'ai effectivement reçu un e-mail signé d'un certain ³Norman Crépin², qui faisait suite à un article de presse dans lequel je démontais scientifiquement le dossier de défense constitué par Floyd Landis publié sur Internet. Le courriel me disait que le laboratoire français était le spécialiste des erreurs à répétition dans ses analyses antidopage et mettait à ma disposition, en pièces jointes, certains documents ceux dont vous venez de me parler ainsi qu'un courriel d'Olivier Rabin, le directeur scientifique de l'AMA, adressé au LNDD. La forme était suspecte, les courriers censés émaner de Châtenay-Malabry non signés par Jacques De Ceaurriz, bref, j'étais très circonspecte. J'ai avertie l'AMA et mes collègues français. Et puis, ce nom, ³Norman Crépin²... Qui est-ce ? » S'il existe bien une personne répondant à ce nom de famille salariée du laboratoire, elle n'a rien à voir avec cette affaire.

Selon nos informations, les policiers de l'OCLCTIC auraient déjà piégé l'auteur de l'envoi d'au moins un courriel, qui serait l'un des membres de l'entourage de Floyd Landis. Le nom du coureur américain revient donc de manière récurrente dans cette affaire, avec, dans son sillage, l'ombre du D Arnie Baker, entraîneur et conseiller de Landis, qui s'est chargé d'orchestrer sur Internet la défense de ce dernier axée, toujours, sur la tendance supposée du laboratoire à multiplier les erreurs.

Alors que les policiers continuent leur enquête dans cette affaire, les laboratoires antidopage continuent donc de subir pressions et attaques de tous styles. Après le dossier Olga Yegorova-EPO et le sabotage non élucidé de l'échantillon B de l'athlète russe (voir L'Équipe du 7 septembre 2001) au sein de ce même laboratoire de Châtenay-Malabry, d'autres structures accréditées par l'AMA essuient des tentatives de déstabilisation grossières et mafieuses. « Auparavant, ces stratégies étaient circonscrites à l'Amérique du Nord, soupire le D Ayotte. Désormais, les attaques personnelles à l'anglo-saxonne se multiplient. Avec l'affaire Armstrong, le dossier Landis, le LNDD est malheureusement gâté. C'est honteux. »

(*) Lance Armstrong, convaincu d'usage d'EPO lors de son premier Tour de France (1999) par le biais d'analyses rétroactives (voir L'Équipe du 23 août 2005) menées par le laboratoire français, ne cesse depuis de remettre en cause la compétence de ce dernier.

SALUT LES AMISHS !

ET S'IL AVAIT VRAIMENT FAIT LE COUP ? Et si Floyd Landis avait vraiment réussi son exploit de Morzine à l'eau claire ? Ou mieux encore, par la seule grâce d'un détonant composé whisky-bière, comme il l'affirme.

Vous imaginez un peu la cruauté de la situation, le sentiment d'impuissance et d'injustice du champion ainsi privé d'un exploit définitivement corrodé par l'acide du doute. On sait, ça paraît dur à avaler. Son histoire, pas le cocktail festif invoqué. À vrai dire, s'il suffisait d'une bonne gueule de bois pour s'enfiler les Saisies et Joux-Plane sur la roue arrière, on connaît quelques joyeux drilles, dont on n'aimerait pas avoir à remonter la descente à vélo, qui seraient en train d'embouteiller l'arrivée sur Morzine.. Mais, en même temps, on a du mal à croire qu'il puisse être aussi benêt, Floyd. Le genre petit vélo équipé d'une paire de sacoches qui traînent par terre et d'un dérailleur à une seule vitesse.

Imaginez-vous un moment à l'arrivée de La Toussuire le moral dans les socquettes blanches.

Immédiatement, vous vous dites : « Tiens, et si je me collais un petit patch de testostérone, je sais bien que c'est plutôt fait pour se sculpter de beaux biscotos que pour relancer la chaudière et que je suis sûr de me faire coincer au premier contrôle mais bon, soyons fous ! »

On veut bien que le sportif professionnel américain considère généralement son corps comme un simple outil de travail totalement « customisable » et cette vieille manie européenne de lutte antidopage comme une entrave ridicule à la liberté d'exercer son job mais tout de même, ça ne tient pas.

Non, non, croyez-moi, commissaire Pillère, il y a du louche là-dessous ! Pas de doute, il a fallu qu'on lui tartine son 4-heures au beurre de cantharide ou qu'on touille son scotch avec une corne de rhinocéros pour que de mâles fluides le poussent ainsi vers la victoire.

Admettons, mais alors, qui aurait fait le coup et pourquoi ? Cherchez : un chef de bande que Landis aurait trahi, une épée à la retraite qu'un succès de l'Américain aurait trop vite poussé vers l'oubli, un taulier vexé qui aurait juré de le poursuivre en enfer et qui serait justement venu faire planer sur la Haute-Savoie une ombre plus inquiétante que celle du milan noir traquant le lapereau ? Vous voyez cette silhouette jaune glissant, subreptice, dans la chambre de Landis pour y jouer son petit remake de J'aurai ta peau avec la conviction vengeresse d'un héros de Mickey Spillane ? Vous avez trouvé le coupable idéal ? Nous aussi ! (Humour, Lance, humour...)

Maintenant, il se pourrait aussi que la dérive fatale de Floyd Landis ne soit que le fruit d'une éducation trop permissive. C'est vrai, ça, malgré leurs coiffes traditionnelles et leur phobie de la télévision, les mennonites de Farmersville, le gros bourg de Pennsylvanie où le Maillot Jaune a grandi, ne sont qu'une bande d'inquiétants

progressistes. Dissidents de la tribu anabaptiste des Anises, les mennonites se sont engagés sur la pente fatale du vice en mettant un jour les doigts dans la prise. Avec l'avènement de la fée électricité sont apparus le frigo indispensable dans le cyclisme moderne, le frigo , le bigoudi chauffant, la télé du voisin, les images du Tour de France et l'appel du vélo de course.

On sait bien qu'un jour les enfants doivent quitter le nid, ça n'est pas absolument une raison pour leur donner de l'élan en les faisant grimper sur une bicyclette.

Eût-il fait partie de la communauté originelle du « vieil ordre Amish », qui professe qu'il ne faut pas « se conformer au monde qui vous entoure » et refuse prudemment l'électricité et les pneus de tracteurs caoutchoutés, que Floyd Landis en serait encore à tenter de s'échapper de Pennsylvanie à draisienne. Et qu'il aurait plus sûrement risqué d'y laisser les semelles de ses godillots que sa réputation !

The World Anti-Doping Code

INTERNATIONAL STANDARD FOR TESTING

version 3.0

June 2003

PREAMBLE

World Anti-Doping Code *International Standard for Testing* is a mandatory *International Standard* developed as part of the World Anti-Doping Program.

The *International Standard for Testing* is extracted from the proposed ISO International Standard for Doping Control (ISO ISDC) which is being prepared by an expert group within the International Anti-Doping Arrangement (IADA) and WADA. The ISO ISDC is based on the IADA International Standard for Doping Control (ISDC)/ISO PAS 18873 (1999). WADA supports and is an active partner with IADA in developing the Proposed ISO ISDC to a full ISO standard. The ISO process is expected to be completed in mid 2004.

Version 1.0 of the *International Standard for Testing* was circulated to *Signatories* and governments for review and comments in November 2002. Version 2.0 was based on the comments and proposals received from *Signatories* and governments.

All *Signatories* and governments were consulted and have had the opportunity to review and provide comments on version 2.0. This draft version 3.0 will be presented for approval to the WADA Executive Committee on June 7th 2003.

The official text of the *International Standard for Testing* shall be maintained by WADA and shall be published in English and French. In the event of any conflict between the English and French versions, the English version shall prevail.

PART ONE: INTRODUCTION, CODE PROVISIONS AND DEFINITIONS

1.0 Introduction and scope

The main purpose of *International Standard for Testing* is to plan for effective *Testing* and to maintain the integrity and identity of the *Samples*, from notifying the *Athlete* to transporting *Samples* for analysis.

The *International Standard for Testing* includes standards for test distribution planning, notification of *Athletes*, preparing for and conducting *Sample* collection, security/post test administration and transport of *Samples*.

The *International Standard for Testing*, including all annexes, is mandatory for all *Signatories* to the *Code*.

The World Anti-Doping Program encompasses all of the elements needed in order to ensure optimal harmonization and best practice in international and national anti-doping programs. The main elements are: the *Code* (Level 1), *International Standards* (Level 2), and Models of Best Practice (Level 3).

In the introduction to the *Code*, the purpose and implementation of the *International Standards* are summarized as follows:

"International Standards for different technical and operational areas within the anti-doping program will be developed in consultation with the Signatories and governments and approved by WADA. The purpose of the International Standards is harmonization among Anti-Doping Organizations responsible for specific technical and operational parts of the anti-doping programs. Adherence to the International Standards is mandatory for compliance with the Code. The International Standards may be revised from time to time by the WADA Executive Committee after reasonable consultation with the Signatories and governments. Unless provided otherwise in the Code, International Standards and all revisions shall become effective on the date specified in the International Standard or revision."

The standards included in the *International Standard for Testing* are extracted from the ISO International Standard for Doping Control (ISO ISDC), which also includes management and support processes for *Testing* activities

Definitions specified in the *Code* are written in italics. Additional definitions specific to the *International Standard for Testing* are underlined.

2.0 Code Provisions

The following articles in the *Code* directly address the *International Standard for Testing*:

Code Article 2 Anti-Doping Rule Violations:

2.3 Refusing, or failing without compelling justification, to submit to *Sample* collection after notification as authorized in applicable anti-doping rules or otherwise evading *Sample* collection.

2.4 Violation of applicable requirements regarding *Athlete* availability for *Out-of-Competition Testing* including failure to provide required whereabouts information and missed tests which are declared based on reasonable rules.

2.5 *Tampering*, or *Attempting* to tamper, with any part of *Doping Control*.

2.8 Administration or *Attempted* administration of a *Prohibited Substance* or *Prohibited Method* to any *Athlete*, or assisting, encouraging, aiding, abetting, covering up or any other type of complicity involving an anti-doping rule violation or any *Attempted* violation.

Code Article 3 Proof of Doping:

3.2.2 Departures from the *International Standard for Testing* which did not cause an *Adverse Analytical Finding* or other anti-doping rule violation shall not invalidate such results. If the *Athlete* establishes that departures from the *International Standard* occurred during *Testing* then the *Anti-Doping Organization* shall have the burden to establish that such departures did not cause the *Adverse Analytical Finding* or the factual basis for the anti-doping rule violation.

Code Article 5 Testing:

5.1 **Test Distribution Planning.** *Anti-Doping Organizations* conducting *Testing* shall in coordination with other *Anti-Doping Organizations* conducting *Testing* on the same *Athlete* pool:

5.1.1 Plan and implement an effective number of *In-Competition* and *Out-of-Competition* tests. Each International Federation shall establish a *Registered Testing Pool* for *International-Level Athletes* in its sport, and each *National Anti-Doping Organization* shall establish a national *Registered Testing Pool* for *Athletes* in its country. The national-level pool shall include *International-Level Athletes* from that country as well as other national-level *Athletes*. Each International Federation and *National Anti-Doping Organization* shall plan and conduct *In-Competition* and *Out-of-Competition Testing* on its *Registered Testing Pool*.

5.1.2 Make *No Advance Notice Testing* a priority.

5.1.3 Conduct *Target Testing*.

5.2 **Standards for Testing.** *Anti-Doping Organizations* conducting *Testing* shall conduct such *Testing* in conformity with the *International Standard for Testing*.

Code Article 7 Results Management:

7.3 Further Review of Adverse Analytical Finding Where Required by Prohibited List. The *Anti-Doping Organization* or other reviewing body established by such organization shall also conduct any follow-up investigation as may be required by the *Prohibited List*. Upon completion of such follow-up investigation, the *Anti-Doping Organization* shall promptly notify the *Athlete* regarding the results of the follow-up investigation and whether or not the *Anti-Doping Organization* asserts that an anti-doping rule was violated.

Code Article 10 Sanctions on Individuals:

10.10 Reinstatement Testing. As a condition to regaining eligibility at the end of a specified period of *Ineligibility*, an *Athlete* must, during any period of *Provisional Suspension* or *Ineligibility*, make him or herself available for *Out-of-Competition Testing* by any *Anti-Doping Organization* having *Testing* jurisdiction, and must, if requested, provide current and accurate whereabouts information. If an *Athlete* subject to a period of *Ineligibility* retires from sport and is removed from *Out-of-Competition Testing* pools and later seeks reinstatement, the *Athlete* shall not be eligible for reinstatement until the *Athlete* has notified relevant *Anti-Doping Organizations* and has been subject to *Out-of-Competition Testing* for a period of time equal to the period of *Ineligibility* remaining as of the date the *Athlete* had retired.

Code Article 14 Confidentiality and Reporting:

14.3 Athlete Whereabouts Information. *Athletes* who have been identified by their International Federation or *National Anti-Doping Organization* for inclusion in an *Out-of-Competition Testing* pool shall provide accurate, current location information. The International Federations and *National Anti-Doping Organizations* shall coordinate the identification of *Athletes* and the collecting of current location information and shall submit it to *WADA*.

WADA shall make this information accessible to other *Anti-Doping Organizations* having authority to test the *Athlete* as provided in Article 15. This information shall be maintained in strict confidence at all times; shall be used exclusively for purposes of planning, coordinating or conducting *Testing*; and shall be destroyed after it is no longer relevant for these purposes.

14.5 Doping Control Information Clearing House. *WADA* shall act as a central clearing house for *Doping Control Testing* data and results for *International-Level Athletes* and national-level *Athletes* that have been included in their *National Anti-Doping Organization's Registered Testing Pool*. To facilitate coordinated test distribution planning and to avoid unnecessary duplication in *Testing* by the various *Anti-Doping Organizations*, each *Anti-Doping Organization* shall report all *In-Competition* and *Out-of-Competition* tests on such *Athletes* to the *WADA* clearinghouse as soon as possible after such tests have been conducted. *WADA* shall make this information accessible to the *Athlete*, the *Athlete's* National Federation, *National Olympic Committee* or *National Paralympic Committee*, *National Anti-Doping Organization*, International Federation, and the International Olympic Committee or International Paralympic Committee. Private information regarding an *Athlete* shall be maintained by *WADA* in strict confidence. *WADA* shall, at least annually, publish statistical reports summarizing such information.

Code Article 15 Clarification of Doping Control Responsibilities:

15.1 Event Testing. The collection of *Samples* for *Doping Control* does and should take place at both *International Events* and *National Events*. However, only a single organization should be responsible for initiating and directing *Testing* during an *Event*. At *International Events*, the collection of *Doping Control Samples* shall be initiated and directed by the

international organization which is the ruling body for the *Event* (e.g., the IOC for the Olympic Games, the International Federation for a World Championship, and PASO for the Pan American Games). If the international organization decides not to conduct any *Testing* at such an *Event*, the *National Anti-Doping Organization* for the country where the *Event* occurs may, in coordination with and with the approval of the international organization or *WADA*, initiate and conduct such *Testing*. At *National Events*, the collection of *Doping Control Samples* shall be initiated and directed by the designated *National Anti-Doping Organization* of that country.

15.2 Out-of-Competition Testing. *Out-of-Competition Testing* is and should be initiated and directed by both international and national organizations. *Out-of-Competition Testing* may be initiated and directed by: (a) *WADA*; (b) the IOC or IPC in connection with the Olympic Games or Paralympic Games; (c) the *Athlete's* International Federation; (d) the *Athlete's National Anti-Doping Organization*; or (e) the *National Anti-Doping Organization* of any country where the *Athlete* is present. *Out-of-Competition Testing* should be coordinated through *WADA* in order to maximize the effectiveness of the combined *Testing* effort and to avoid unnecessary repetitive *Testing* of individual *Athletes*.

15.4 Mutual Recognition. Subject to the right to appeal provided in Article 13, the *Testing*, therapeutic use exemptions and hearing results or other final adjudications of any *Signatory* which are consistent with the *Code* and are within that *Signatory's* authority, shall be recognized and respected by all other *Signatories*. *Signatories* may recognize the same actions of other bodies which have not accepted the *Code* if the rules of those bodies are otherwise consistent with the *Code*.

3.0 Terms and definitions

3.1 Defined terms from the Code

Adverse Analytical Finding: A report from a laboratory or other approved *Testing* entity that identifies in a *Specimen* the presence of a *Prohibited Substance* or its *Metabolites* or *Markers* (including elevated quantities of endogenous substances) or evidence of the *Use* of a *Prohibited Method*.

Anti-Doping Organization: A *Signatory* that is responsible for adopting rules, for initiating, implementing or enforcing any part of the *Doping Control* process. This includes, for example, the International Olympic Committee, the International Paralympic Committee, other *Major Event Organizations* that conduct *Testing* at their *Events*, *WADA*, International Federations, and *National Anti-Doping Organizations*.

Athlete: For purposes of *Doping Control*, any *Person* who participates in sport at the international level (as defined by each International Federation) or national level (as defined by each *National Anti-Doping Organization*) and any additional *Person* who participates in sport at a lower level if designated by the *Person's National Anti-Doping Organization*. For purposes of anti-doping information and education, any *Person* who participates in sport under the authority of any *Signatory*, government, or other sports organization accepting the *Code*.

Code: The World Anti-Doping Code.

Competition: A single race, match, game or singular athletic contest. For example, the finals of the Olympic 100-meter dash. For stage races and other athletic contests where prizes are awarded on a daily or other interim basis, the distinction between a *Competition* and an *Event* will be as provided in the rules of the applicable International Federation.

Consequences of Anti-Doping Rules Violations: An *Athlete's* or other *Person's* violation of an anti-doping rule may result in one or more of the following: (a) Disqualification means the *Athlete's* results in a particular *Competition* or *Event* are invalidated, with all resulting consequences including forfeiture of any medals, points and prizes; (b) Ineligibility means the *Athlete* or other *Person* is barred for a specified period of time from participating in any *Competition* or other activity or funding as provided in Article 10.9; and (c) Provisional Suspension means the *Athlete* or other *Person* is barred temporarily from participating in any *Competition* prior to the final decision at a hearing conducted under Article 8 (Right to a Fair Hearing).

Doping Control: The process including test distribution planning, *Sample* collection and handling, laboratory analysis, results management, hearings and appeals.

Event: A series of individual *Competitions* conducted together under one ruling body (e.g., the Olympic Games, FINA World Championships, or Pan American Games).

In-Competition: For purposes of differentiating between *In-Competition* and *Out-of-Competition Testing*, unless provided otherwise in the rules of an International Federation or other relevant *Anti-Doping Organization*, an *In-Competition* test is a test where an *Athlete* is selected for *Testing* in connection with a specific *Competition*.

Independent Observer Program: A team of observers, under the supervision of WADA, who observe the *Doping Control* process at certain *Events* and report on observations. If WADA is *Testing In-Competition* at an *Event*, the observers shall be supervised by an independent organization.

Ineligibility: See *Consequences of Anti-Doping Rules Violations* above.

International Event: An *Event* where the International Olympic Committee, the International Paralympic Committee, an International Federation, a *Major Event Organization*, or another international sport organization is the ruling body for the *Event* or appoints the technical officials for the *Event*.

International-Level Athlete: *Athletes* designated by one or more International Federations as being within the *Registered Testing Pool* for an International Federation.

International Standard: A standard adopted by WADA in support of the *Code*. Compliance with an *International Standard* (as opposed to another alternative standard, practice or procedure) shall be sufficient to conclude that the procedures addressed by the *International Standard* were performed properly.

Minor: A natural *Person* who has not reached the age of majority as established by the applicable laws of his or her country of residence.

National Anti-Doping Organization: The entity(ies) designated by each country as possessing the primary authority and responsibility to adopt and implement anti-doping rules, direct the collection of *Samples*, the management of test results, and the conduct of hearings, all at the national level. If this designation has not been made by the competent public authority (ies), the entity shall be the country's *National Olympic Committee* or its designee.

National Olympic Committee: The organization recognized by the International Olympic Committee. The term *National Olympic Committee* shall also include the National Sport Confederation in those countries where the National Sport Confederation assumes typical *National Olympic Committee* responsibilities in the anti-doping area.

No Advance Notice: A *Doping Control* which takes place with no advance warning to the *Athlete* and where the *Athlete* is continuously chaperoned from the moment of notification through *Sample* provision.

Out-of-Competition: Any *Doping Control* which is not *In-Competition*.

Prohibited List: The List identifying the *Prohibited Substances* and *Prohibited Methods*.

Provisional Suspension: See *Consequences* above.

Registered Testing Pool: The pool of top level *Athletes* established separately by each International Federation and *National Anti-Doping Organization* who are subject to both *In-Competition* and *Out-of-Competition Testing* as part of that International Federation's or Organization's test distribution plan.

Sample/Specimen: Any biological material collected for the purposes of *Doping Control*.

Signatories: Those entities signing the *Code* and agreeing to comply with the *Code*, including the International Olympic Committee, International Federations, International Paralympic Committee, *National*

Olympic Committees, National Paralympic Committees, Major Event Organizations, National Anti-Doping Organizations, and WADA.

Target Testing: Selection of *Athletes* for *Testing* where specific *Athletes* or groups of *Athletes* are selected on a non-random basis for *Testing* at a specified time.

Testing: The parts of the *Doping Control* process involving test distribution planning, *Sample* collection, *Sample* handling, and *Sample* transport to the laboratory.

WADA: The World Anti-Doping Agency.

3.2 Defined Terms from the *International Standard for Testing*

Blood Collection Official: An official who is qualified to and has been authorized by the *ADO* to collect a blood *Sample* from an *Athlete*.

Chain of Custody: The sequence of individuals or organizations who have the responsibility for a *Sample/specimen* from the provision of the sample/specimen until the *Sample/specimen* has been received for analysis.

Chaperone: An official who is trained and authorized by the *ADO* to carry out specific duties including notification of the *Athlete* selected for *Sample* collection, accompanying and observing the *Athlete* until arrival at the *Doping Control Station*, and/or witnessing and verifying the provision of the *Sample* where the training qualifies him/her to do so.

Doping Control Officer: An official who has been trained and authorised by the *ADO* with delegated responsibility for the on-site management of a *Sample Collection Session*.

Doping Control Station: The location where the *Sample Collection Session* will be conducted.

Failure to Comply: A term used to describe *Anti-Doping Rule Violations* in Articles 2.3, 2.4, 2.5 and 2.8 of the Code.

Sample Collection Equipment: Containers or apparatus used to directly collect or hold the *Athlete's Specimen* at any time during the *Sample* collection process. *Sample Collection Equipment* shall, as a minimum, consist of:

- For urine *Sample* collection:
 - Collection vessels for collecting the urine *Sample* as it leaves the *Athlete's* body;
 - Sealable and tamper-evident bottles and lids for securing the urine *Sample*;

- For blood *Sample* collection:
 - Needles for collecting the blood *Sample*;
 - Blood tubes with sealable and tamper-evident devices for holding the blood *Sample*.

Sample Collection Personnel: A collective term for qualified officials authorised by the *ADO* who may carry out or assist with duties during the *Sample Collection Session*.

Sample Collection Session: All of the sequential activities that directly involve the *Athlete* from notification until the *Athlete* leaves the Doping Control Station after having provided his/her *Sample/s*.

Weighted: A ranking method of selecting *Athletes* using criteria where the ranking is based on the potential risk of doping and possible doping patterns.

PART TWO: STANDARDS FOR TESTING

4.0 Planning

4.1 Objective

The objective is to plan and implement an effective distribution of *Athlete* tests.

4.2 General

Planning starts with establishing criteria for *Athletes* to be included in a *Registered Testing Pool* and ends with selecting *Athletes* for *Sample* collection.

The main activities are information gathering, risk evaluation, and developing, monitoring, evaluating and modifying the test distribution plan.

4.3 Requirements for establishing the *Registered Testing Pool*

4.3.1 The *Anti-Doping Organization* (ADO) shall define and document the criteria for *Athletes* to be included in a *Registered Testing Pool*. This shall include as a minimum:

- For International Federations (IFs):
Athletes who compete at a high level of international competition, and
- For *National Anti-Doping Organizations*:
Athletes who are part of national teams in Olympic and Paralympic sports and recognised national federations.

The criteria shall be reviewed at least annually and updated if required.

4.3.2 The ADO shall include *Athletes* under their authority in the *Registered Testing Pool* who are serving periods of *Ineligibility* or *Provisional Suspensions* as *Consequences of Anti-Doping Rules Violations*.

4.3.3 The *Registered Testing Pool* shall be reviewed and updated regularly to reflect changes in *Athletes'* competing levels to ensure additions to or removals from the pool as required.

4.4 Requirements for collecting *Athlete* whereabouts information for the purposes of Out of Competition Testing

4.4.1 The ADO shall define procedures and/or systems for:

- a) Collecting, maintaining and monitoring sufficient whereabouts information to ensure that *Sample* collection can be planned and conducted at *No Advance Notice* for all *Athletes* included in the *Registered Testing Pool*, and
- b) When *Athletes* fail to provide accurate and timely whereabouts information, taking appropriate action to ensure the information stays up to date and complete.

4.4.2 As a minimum the following *Athlete* whereabouts information shall be collected:

- a) Name
- b) Sport/discipline,
- c) Home address
- d) Contact phone numbers
- e) Training times and venues
- f) Training camps
- g) Travel plans
- h) Competition schedule
- i) Disability if applicable, including the requirement for third party involvement in notification.

4.5 Requirements for test distribution planning

4.5.1 The ADO shall, as a minimum, evaluate the potential risk of doping and possible doping pattern for each sport and/or discipline based on:

- a) Physical demands of the sport and possible performance enhancing effect that doping may elicit;
- b) Available doping analysis statistics;
- c) Available research on doping trends;
- d) Training periods and *Competition* season.

4.5.2 The ADO shall develop and document a test distribution plan based on information determined in 4.5.1, the number of *Athletes* per sport/discipline in the *Registered Testing Pool* and the evaluation outcomes of previous test distribution planning cycles.

4.5.3 The ADO shall allocate the number of *Sample* collections by type of *Sample* collection for each sport/discipline, including *No Advance Notice*, *Out-of-Competition*, *In-Competition*, blood and urine *Sample* collection, as required to achieve effective deterrence.

4.5.4 The ADO shall establish a system whereby the test distribution plan is reviewed and, if necessary, updated on a regular basis in order to incorporate new information and take into account *Sample* collection from *Athletes* in the *Registered Testing Pool* by other ADOs.

4.5.5 The ADO shall establish a system for maintaining test distribution planning data. Such data shall be used to assist with determining whether modifications to the plan are necessary. This information shall include as a minimum:

For each test:

- a) The sport/discipline;
- b) The country represented by the *Athlete* (if applicable);
- c) The type of *Sample* collection (*No Advance Notice*, *Out-of-Competition*, *In-Competition* or advance notice);
- d) The date of *Sample* collection; and
- e) The country in which the *Sample* collection occurred.

In addition, for each *Adverse Analytical Finding*:

- a) Dates of *Sample* collection and analysis;
- b) Class of substance/s found;
- c) Actual substance/s detected;
- d) *Sanctions of Anti-Doping Rules Violations*, if any.

4.5.6 The ADO shall ensure that the athlete support personnel shall not be involved in the test distribution planning for their athletes.

4.5.7 In planning and conducting tests at *International Event*, and where the relevant IF does not have a doping control program that complies with this standard, the *National Anti-Doping Organization* shall be the preferred *Sample* collection supplier.

4.6 Requirements for selection of *Athletes*

4.6.1 In accordance with the number of *Sample* collections allocated to each sport/discipline in the test distribution plan, the ADO shall select *Athletes* for *Sample* collection using *Target Testing*, Weighted and random selection methods.

4.6.2 As a minimum, the *ADO* shall consider *Target Testing Athletes* based on the following information:

- a) Injury;
- b) Withdrawal or absence from expected *Competition*;
- c) Going into or coming out of retirement;
- d) Behaviour indicating doping;
- e) Sudden major improvements in performance;
- f) Changes in *Athlete* whereabouts information that can indicate a potential increase in the risk of doping, including moving to a remote location;
- g) *Athlete* sport performance history;
- h) Details of past *Doping Controls*;
- i) *Athlete* reinstatement after a period of *Ineligibility*; and
- j) Reliable information from a third party.

4.6.3 An *ADO* may select *Athletes* under their authority for *Sample* collection who are not included in the *Registered Testing Pool* defined in 4.3.1 and 4.3.2.

4.6.4 Where the *ADO* authorises a Doping Control Officer (DCO) to select *Athletes* for *Sample* collection, the *ADO* shall provide selection criteria to the DCO in accordance with the test distribution plan.

4.6.5 Following the selection of an *Athlete* for *Sample* collection and prior to notification of the *Athlete*, the *ADO* and/or DCO shall ensure *Athlete* selection decisions are disclosed only to those who need to know in order to ensure the *Athlete* can be notified and tested on a *No Advance Notice* basis.

5.0 Notification of Athletes

5.1 Objective

To ensure that the selected *Athlete* is notified, the rights of the *Athlete* are maintained, there are no opportunities to manipulate the *Sample* to be provided and the notification is documented.

5.2 General

Notification of *Athletes* starts when the *ADO* initiates the notification of the selected *Athlete* and ends when the *Athlete* arrives at the Doping Control Station or when the *Athlete's* possible failure to comply is brought to the *ADO's* attention.

The main activities are:

- a) Appointment of DCOs, Chaperones and other Sample Collection Personnel;
- b) Locating the *Athlete* and confirming his/her identity;
- c) Informing the *Athlete* that he/she has been selected to provide a *Sample* and of his/her rights and responsibilities;
- d) For *No Advance Notice Sample* collection, continuously chaperoning the *Athlete* from the time of notification to the arrival at the designated Doping Control Station; and
- e) Documenting the notification.

5.3 Requirements prior to notification of *Athletes*

5.3.1 *No Advance Notice* shall be the notification method for *Out-of-Competition Sample* collection whenever possible.

5.3.2 To conduct or assist with Sample Collection Sessions, the ADO shall appoint and authorise Sample Collection Personnel who have been trained for their assigned responsibilities, who do not have a conflict of interest in the outcome of the *Sample* collection, and who are not *Minors*.

5.3.3 Sample Collection Personnel shall have official identification that is provided and controlled by the ADO. The minimum identification requirement is an official card/document naming the ADO through which they have been authorised. For DCOs, additional identification requirements shall include their name, their photograph and the card's/document's expiry date. For Blood Collection Officials additional identification requirements include evidence of their professional training in the collection of blood *Samples*.

5.3.4 The ADO shall establish criteria to validate the identity of an *Athlete* selected to provide a *Sample*. This ensures the selected *Athlete* is the *Athlete* who is notified.

5.3.5 The ADO, DCO or Chaperone, as applicable, shall establish the location of the selected *Athlete* and plan the approach and timing of notification, taking into consideration the specific circumstances of the sport/*Competition* and the situation in question.

5.3.6 For *Out-of-Competition Sample* collection, the ADO shall establish criteria to ensure that reasonable attempts are made to notify *Athletes* of their selection for *Sample* collection.

5.3.7 Reasonable attempts shall be defined by the ADO and at a minimum shall consider alternative times of day/evening and alternative locations over a specified period of time from the initial notification attempt.

5.3.8 The *ADO* shall establish a system for logging *Athlete* notification attempt/s and outcome/s.

5.3.9 The *Athlete* shall be the first one notified that he/she has been selected for *Sample* collection except where prior contact with a third party is required as specified in 5.3.10.

5.3.10 The *ADO/DCO/Chaperone*, as applicable, shall consider whether a third party is required to be notified prior to notification of the *Athlete* when the *Athlete* is a *Minor*, where required by an *Athlete's* disability as provided for in Annex B - Modifications for *Athletes* with disabilities, or in situations where an interpreter is required for the notification.

5.3.11 If the *Athlete* can not be contacted after having made reasonable attempts using the information supplied in 4.4.2 and logging the attempts in accordance with 5.3.8, the *DCO* or *ADO*, as applicable, shall institute Annex A – Investigating a possible failure to comply.

5.3.12 The *ADO* shall not re-schedule or change a *Sample* collection from *No Advance Notice* to advance notice except where an unexpected situation forces the need for an advanced notice *Sample* collection. Any such decision shall be recorded.

5.3.13 Notification for advance notice *Sample* collection shall be by any means that indicates the *Athlete* received the notice.

5.4 Requirements for notification of *Athletes*

5.4.1 When initial contact is made, the *ADO*, *DCO* or *Chaperone*, as applicable, shall ensure that the *Athlete* and/or a third party if required in accordance with 5.3.10, is informed:

- a) That the *Athlete* is required to undergo a *Sample* collection;
- b) Of the authority under which the *Sample* collection is to be conducted;
- c) Of the type of *Sample* collection and any conditions that need to be adhered to prior to the *Sample* collection;
- d) Of the *Athlete's* rights, including the right to:
 - i. Have a representative and, if required, an interpreter;
 - ii. Ask for additional information about the *Sample* collection process;
 - iii. Request a delay in reporting to the Doping Control Station for valid reasons; and
 - iv. Request modifications as provided for in Annex B – Modifications for *Athletes* with disabilities.
- e) Of the *Athlete's* responsibilities, including the requirement to:

- i. Remain within sight of the DCO/Chaperone at all times from the first moment of in-person notification by the DCO/Chaperone until the completion of the *Sample* collection procedure;
 - ii. Produce identification in accordance with 5.3.4; and
 - iii. Comply with *Sample* collection procedures and the possible consequences of failure to comply; and
 - iv. Report to the Doping Control Station, unless delayed for valid reasons, as soon as possible and within 60 minutes of notification for a *No Advance Notice Sample* collection and 24 hours of receipt of notification for an advance notice *Sample* collection.
- f) Of the location of the Doping Control Station.

5.4.2 When in-person contact is made, the DCO/Chaperone shall:

- a) From this time until the *Athlete* leaves the Doping Control Station at the end of his/her Sample Collection Session, keep the *Athlete* under observation at all times.
- b) Identify themselves to the *Athlete* using their official ADO identification card/document;
- c) Confirm the *Athlete's* identity as per the criteria established in 5.3.4. Any failure to confirm the identity of the *Athlete* shall be documented. In such cases, the DCO responsible for conducting the Sample Collection Session shall decide whether it is appropriate to report the situation in accordance with Annex A – Investigating a possible failure to comply.

5.4.3 The Chaperone/DCO shall then have the *Athlete* sign an appropriate form to acknowledge and accept the notification. If the *Athlete* refuses to sign that he/she has been notified or evades the notification, the Chaperone/DCO shall inform the *Athlete* of the consequences of failing to comply if possible, and the Chaperone (if not the DCO) shall immediately report all relevant facts to the DCO. When possible the DCO shall continue to collect a *Sample*. The DCO shall document the facts and report the circumstances to the ADO. The DCO and ADO shall follow the steps prescribed in Annex A – Investigating a possible failure to comply.

5.4.4 The DCO/Chaperone shall consider any reasonable request by the *Athlete* to delay reporting to the Doping Control Station within 60 mins of acknowledgement and acceptance of notification and approve or reject such requests as appropriate in accordance with 5.4.5 and 5.4.6. The DCO shall document the reasons for any such delay that may require further investigation by the ADO. The first urine *Sample* post notification shall be collected.

5.4.5 A DCO may accept a request from an *Athlete* to delay reporting to the Doping Control Station beyond 60 mins, and/or once the athlete arrives at the Doping Control Station and wishes to leave if the *Athlete*

can be continuously chaperoned during the delay and if the request relates to the following activities:

- a) Participation in a victory ceremony;
- b) Fulfilment of media commitments;
- c) Competing in further *competitions*;
- d) Performing a warm down;
- e) Obtaining necessary medical treatment;
- f) Locating a representative and/or interpreter.

The DCO shall document the reasons for delay in reporting to the Doping Control Station and/or reasons for leaving the Doping Control Station once arriving that may require further investigation by the *ADO*.

5.4.6 A DCO/Chaperone shall reject a request for delay from an *Athlete* if it will not be possible for the *Athlete* to be continuously chaperoned.

5.4.7 When an *Athlete* notified of an advance notice *Sample* collection does not report to the Doping Control Station at the designated time, the DCO shall use his/her judgement whether to attempt to contact the *Athlete*. At a minimum, the DCO shall wait 30 minutes after the appointed time before departing. If the *Athlete* still has not reported by the time the DCO departs, the DCO shall follow the requirements of Annex A – Investigating a possible failure to comply.

5.4.8 If the *Athlete* reports to the Doping Control Station after the minimum waiting time and prior to the DCO's departure, the DCO shall decide as to whether to process a possible failure to comply. If at all possible the DCO shall proceed with collecting a *Sample*, and shall document the details of the delay in the *Athlete* reporting to the Doping Control Station.

5.4.9 If, while keeping the *Athlete* under observation, Sample Collection Personnel observe any matter with potential to compromise the test, the circumstances shall be reported to and documented by the DCO. If deemed appropriate by the DCO, the DCO shall follow the requirements of Annex A – Investigating a possible failure to comply.

6.0 Preparing for the Sample Collection Session

6.1 Objective

To prepare for the Sample Collection Session in a manner that ensures that the session can be conducted efficiently and effectively.

6.2 General

Preparing for the Sample Collection Session starts with the establishment of a system for obtaining relevant information for effective conduct of the session and ends when it is confirmed that the Sample Collection Equipment conforms to the specified criteria.

The main activities are:

- a) Establishing a system for collecting details regarding the Sample Collection Session;
- b) Establishing criteria for who may be authorised to be present during a Sample Collection Session;
- c) Ensuring that the Doping Control Station meets the minimum criteria prescribed in 6.3.2;
- d) Ensuring that Sample Collection Equipment used by the ADO meets the minimum criteria prescribed in 6.3.4.

6.3 Requirements for preparing for the Sample Collection Session

6.3.1 The ADO shall establish a system for obtaining all the information necessary to ensure that the Sample Collection Session can be conducted effectively, including special requirements to meet the needs of *Athletes* with disabilities as provided in Annex B – Modifications for *Athletes* with disabilities.

6.3.2 The DCO shall use a Doping Control Station which, at a minimum, ensures the *Athlete's* privacy and is used solely as a Doping Control Station for the duration of the Sample Collection Session. The DCO shall record any significant deviations from these criteria.

6.3.3 The ADO shall establish criteria for who may be authorised to be present during the Sample Collection Session in addition to the Sample Collection Personnel. At a minimum the criteria shall include:

- a) An *Athlete's* entitlement to be accompanied by a representative and/or interpreter during the Sample Collection Session except when the *Athlete* is passing a urine *Sample*.
- b) A *Minor Athlete's* entitlement, and the witnessing DCO/Chaperone's entitlement to have a representative observe the Chaperone when the *Minor Athlete* is passing a urine *Sample*, but without the representative directly observing the passing of the *Sample* unless requested to do so by the *Minor Athlete*.
- c) An *Athlete* with a disability's entitlement to be accompanied by a representative as provided for in Annex B - Modifications for *Athletes* with disabilities.

- d) A WADA Independent Observer where applicable under the *Independent Observer Program*. The WADA Independent Observer shall not directly observe the passing of a urine *Sample*.

6.3.4 The DCO shall only use Sample Collection Equipment systems that are authorised by the ADO, which at a minimum, shall meet the following criteria. They shall:

- a) Have a unique numbering system incorporated into all bottles, containers, tubes or any other item used to seal the *Athlete's Sample*;
- b) Have a sealing system that is tamper evident;
- c) Ensure the identity of the *Athlete* is not evident from the equipment itself;
- d) Ensure that all equipment is clean and sealed prior to use by the *Athlete*.

7.0 Conducting the Sample Collection Session

7.1 Objective

To conduct the Sample Collection Session in a manner that ensures the integrity, security and identity of the *Sample* and respects the privacy of the *Athlete*.

7.2 General

The Sample Collection Session starts with defining overall responsibility for the conduct of the Sample Collection Session and ends once the *Sample* collection documentation is complete.

The main activities are:

- a) Preparing for collecting the *Sample*;
- b) Collecting the *Sample*; and
- c) Documenting the *Sample* collection.

7.3 Requirements prior to Sample collection

7.3.1 The ADO shall be responsible for the overall conduct of the Sample Collection Session with specific responsibilities delegated to the DCO.

7.3.2 The DCO shall ensure that the *Athlete* is informed of his/her rights and responsibilities as specified in 5.4.1.

7.3.3 The DCO shall provide the *Athlete* with the opportunity to hydrate.

7.3.4 The *Athlete* shall only leave the Doping Control Station under continuous observation by the DCO/Chaperone and with the approval of the DCO. The DCO shall consider any reasonable request by the *Athlete* to leave the Doping Control Station, as specified in 5.4.5 and 5.4.6, until the *Athlete* is able to provide a *Sample*.

7.3.5 If the DCO gives approval for the *Athlete* to leave the Doping Control Station, the DCO shall agree with the *Athlete* on:

- a) The purpose of the *Athlete* leaving the Doping Control Station; and
- b) The time of return (or return upon completion of an agreed activity).

The DCO shall document this information and the actual time of the *Athlete's* departure and return.

7.4 Requirements for *Sample* collection

7.4.1 The DCO shall collect the *Sample* from the *Athlete* according to the following protocol/s for the specific type of *Sample* collection:

- a) Annex C: Collection of urine *Samples*
- b) Annex D: Collection of blood *Samples*

7.4.2 Any behaviour by the *Athlete* and/or persons associated with the *Athlete* or anomalies with potential to compromise the *Sample* collection shall be recorded. If appropriate, the *ADO* and/or DCO, as applicable, shall institute Annex A – Investigating a possible failure to comply.

7.4.3 If there are doubts as to the origin or authenticity of the *Sample*, the *Athlete* shall be asked to provide an additional *Sample*. If the *Athlete* refuses to provide an additional *Sample* the DCO shall institute Annex A – Investigating a possible failure to comply.

7.4.4 The DCO shall provide the *Athlete* with the opportunity to document any concerns he/she may have about how the session was conducted.

7.4.5 In conducting the Sample Collection Session the following information shall be recorded as a minimum:

- a) Date, time and type of notification (*No Advance Notice*, advance notice, *In-Competition* or *Out-of-Competition*);
- b) Date and time of *Sample* provision;
- c) The name of the *Athlete*;
- d) The date of birth of the *Athlete*;

- e) The gender of the *Athlete*;
- f) The *Athlete's* home address and telephone number;
- g) The *Athlete's* sport and discipline;
- h) The *Sample* code number;
- i) The name and signature of the Chaperone who witnessed the urine *Sample* provision;
- j) The name and signature of the Blood Collection Official who collected the blood *Sample*, where applicable;
- k) Required laboratory information on the *Sample*;
- l) Medications and supplements taken and recent blood transfusion details if applicable, within the timeframe specified by the lab as declared by the *Athlete*;
- m) Any irregularities in procedures;
- n) *Athlete* comments or concerns regarding the conduct of the session, if provided;
- o) The name and signature of the *Athlete*;
- p) The name and signature of the *Athlete's* representative, if required; and
- q) The name and signature of the DCO.

7.4.6 The *Athlete* and DCO shall sign appropriate documentation to indicate their satisfaction that the documentation accurately reflects the details of the *Athlete's Sample Collection Session*, including any concerns recorded by the *Athlete*. The *Athlete's* representative shall sign on behalf of the *Athlete* if the *Athlete* is a *Minor*. Other persons present who had a formal role during the *Athlete's Sample Collection Session* may sign the documentation as a witness of the proceedings.

7.4.7 The DCO shall provide the *Athlete* with a copy of the records of the Sample Collection Session that have been signed by the *Athlete*.

8.0 Security/Post test administration

8.1 Objective

To ensure that all *Samples* collected at the Doping Control Station and *Sample* collection documentation are securely stored prior to their departure from the Doping Control Station.

8.2 General

Post test administration begins when the *Athlete* has left the Doping Control Station after providing his/her *Sample/s*, and ends with preparation of all of the collected *Samples* and documentation for transport.

8.3 Requirements for Security/post test administration

8.3.1 The *ADO* shall define criteria ensuring that any sealed *Sample* will be stored in a manner that protects its integrity, identity and security prior to transport from the Doping Control Station. The *DCO* shall ensure that any sealed *Sample* is stored in accordance with these criteria.

8.3.2 Without exception, all *Samples* collected shall be sent for analysis to a *WADA* accredited laboratory or as otherwise approved by *WADA*.

8.3.3 The *ADO/DCO* shall develop a system to ensure that the documentation for each sealed *Sample* is completed and securely handled.

8.3.4 The *ADO* shall develop a system to ensure that, where required, instructions for the type of analysis to be conducted are provided to the *WADA* accredited laboratory or as otherwise approved by *WADA*.

9.0 Transport of Samples and documentation

9.1 Objective

- a) To ensure that *Samples* and related documentation arrive at the *WADA* accredited laboratory or as otherwise approved by *WADA* in proper condition to do the necessary analysis, and
- b) To ensure the *Sample Collection Session* documentation is sent by the *DCO* to the *ADO* in a secure and timely manner.

9.2 General

Transport starts when the sealed *Samples* and documentation leave the Doping Control Station and ends with the confirmed receipt of the *Samples* and *Sample* collection documentation at their intended destinations.

The main activities are arranging for the secure transport of *Samples* and related documentation to the *WADA* accredited laboratory or as otherwise approved by *WADA*, and arranging for the secure transport of *Sample* collection documentation to the *ADO*.

9.3 Requirements for transport of *Samples* and documentation

9.3.1 The *ADO* shall authorise a transport system that ensures *Samples* and documentation will be transported in a manner that protects their integrity, identity and security.

9.3.2 The *ADO* shall develop a system for recording the Chain of Custody of the *Samples* and *Sample* collection documentation which includes confirming that both the *Samples* and *Sample* collection documentation have arrived at their intended destinations.

9.3.3 Sealed *Samples* shall always be transported to the *WADA* accredited laboratory or as otherwise approved by *WADA*, using the *ADO's* authorised transport method as soon as practicable after the completion of the Sample Collection Session.

9.3.4 Documentation identifying the *Athlete* shall not be included with the *Samples* or documentation sent to the *WADA* accredited laboratory or as otherwise approved by *WADA*.

9.3.5 The DCO shall send all relevant Sample Collection Session documentation to the *ADO* using the *ADO's* authorised transport method as soon as practicable after the completion of the Sample Collection Session.

9.3.6 Chain of Custody shall be checked by the *ADO* if receipt of either the *Samples* with accompanying documentation or *Sample* collection documentation is not confirmed at their intended destination or a *Sample's* integrity or identity may have been compromised during transport. In this instance, the *ADO* shall consider whether the *Sample* should be voided.

PART THREE: ANNEXES

Annex A - Investigating a possible failure to comply

A.1 Objective

To ensure that any matters occurring before, during or after a Sample Collection Session that may lead to a determination of a failure to comply are assessed, acted upon and documented.

A.2 Scope

Investigating a possible failure to comply begins when the *ADO* or a *DCO* becomes aware of a matter with the potential to compromise an *Athlete's* test and ends when the *ADO* takes appropriate follow-up action based on the outcomes of its investigation into the possible failure to comply.

A.3 Responsibility

A.3.1 The *ADO* is responsible for ensuring that:

- a) Any matters with the potential to compromise an Athlete's test are assessed to determine if a possible failure to comply has occurred;
- b) All relevant information, including information from the immediate surroundings when applicable, is obtained as soon as possible or when practicable to ensure that all knowledge of the matter can be reported and be presented as possible evidence; and
- c) Appropriate documentation is completed to report any possible failure to comply.

A.3.2 Sample Collection Personnel are responsible for reporting to the *DCO* any matter with the potential to compromise a test, and the *DCO* is responsible for reporting such matters to the *ADO*.

A.4 Requirements

A.4.1 Any matters with the potential to compromise the test shall be reported as soon as practicable.

A.4.2 If the matter has potential to compromise the test, the *Athlete* shall be notified if possible:

- a) Of the possible consequences;
- b) That a possible failure to comply will be investigated by the *ADO* and appropriate follow-up action will be taken.

A.4.3 The necessary information about the possible failure to comply shall be obtained from all relevant sources as soon as possible and recorded.

A.4.4 If possible, the *Athlete's Sample Collection Session* shall be completed.

A.4.5 The *ADO* shall establish a system for ensuring that the outcomes of its investigation into the possible failure to comply are considered for results management action and, if applicable, for further planning and *Testing*.

Annex B - Modifications for *Athletes* with disabilities

B.1 Objective

To ensure that the special needs of *Athletes* with disabilities are provided as much as possible in relation to the provision of a *Sample*.

B.2 Scope

The scope of determining whether modifications need to be considered starts with identification of situations where *Sample* collection involves *Athletes* with disabilities and ends with the necessary modifications to *Sample* collection procedures and equipment as possible for these *Athletes*.

B.3 Responsibility

The *ADO* has responsibility for ensuring, when possible, that the *DCO* has any information and *Sample Collection Equipment* necessary to conduct a *Sample Collection Session* with an *Athlete* with a disability. The *DCO* has responsibility for the *Sample* collection.

B.4 Requirements

B.4.1 All aspects of notification and *Sample* collection for *Athletes* with disabilities shall be carried out in accordance with the standard notification and *Sample* collection procedures unless modifications are necessary due to the *Athlete's* disability.

B.4.2 In planning or arranging *Sample* collection, the *ADO* and *DCO* shall consider whether there will be any *Sample* collection for *Athletes* with disabilities that may require modifications to the standard procedures for notification or *Sample* collection, including *Sample Collection Equipment* and facilities.

B.4.3 The *DCO* shall have the authority to make modifications as the situation requires when possible and as long as such modifications will not compromise the identity, security or integrity of the *Sample*.

B.4.4 For *Athletes* with a physical disability or a sensorial disability, the *Athlete* can be assisted by the *Athlete's* representative or *Sample Collection Personnel* during the *Sample Collection Session* where authorised by the *Athlete* and agreed to by the *DCO*.

B.4.5 For *Athletes* with an intellectual disability, the *ADO* or *DCO* shall determine whether the *Athlete* must have a representative at the *Sample Collection Session* and the nature of the assistance that the representative must provide. Additional assistance can be provided by the representative or *Sample Collection Personnel* during the *Sample Collection Session* where authorised by the *Athlete* and agreed to by the *DCO*.

B.4.6 The DCO can decide that alternative Sample Collection Equipment or facilities will be used when required to enable the *Athlete* to provide the *Sample* as long as the *Sample's* identity, security and integrity will not be affected.

B.4.7 *Athletes* who are using urine collection or drainage systems are required to eliminate existing urine from such systems before providing a urine *Sample* for analysis.

B.4.8 The DCO will record modifications made to the standard *Sample* collection procedures for *Athletes* with disabilities, including any applicable modifications specified in the above actions.

Annex C - Collection of urine *Samples*

C.1 Objective

To collect an *Athlete's* urine *Sample* in a manner that ensures:

- a) Consistency with relevant principles of internationally recognised standard precautions in healthcare settings so that the health and safety of the *Athlete* and Sample Collection Personnel are not compromised;
- b) The *Sample* is of a quality and quantity that meets laboratory guidelines;
- c) The *Sample* is clearly and accurately identified; and
- d) The *Sample* is securely sealed.

C.2 Scope

The collection of a urine *Sample* begins with ensuring the *Athlete* is informed of the *Sample* collection requirements and ends with discarding any residual urine remaining at the end of the *Athlete's* Sample Collection Session.

C.3 Responsibility

The DCO has the responsibility for ensuring that each *Sample* is properly collected, identified and sealed. The DCO/Chaperone has the responsibility for directly witnessing the passing of the urine *Sample*.

C.4 Requirements

C.4.1 The DCO shall ensure that the *Athlete* is informed of the requirements of the *Sample* collection, including any modifications as provided for in Annex B – Modifications for *Athletes* with disabilities.

C.4.2 The DCO shall ensure that the *Athlete* is offered a choice of appropriate equipment for collecting the *Sample*. If the nature of an *Athlete's* disability requires that he/she must use additional or other equipment as provided for in Annex B – Modifications for *Athletes* with disabilities, the DCO shall inspect that equipment to ensure that it will not affect the identity or integrity of the *Sample*.

C.4.3 The DCO shall instruct the *Athlete* to select a collection vessel.

C.4.4 When the *Athlete* selects a collection vessel and for selection of all other Sample Collection Equipment that directly holds the urine *Sample*, the DCO will instruct the *Athlete* to check that all seals on the selected equipment are intact and the equipment has not been tampered with. If the *Athlete* is not satisfied with the selected equipment, he/she may select another. If the *Athlete* is not satisfied with any of the equipment available for the selection, this shall be recorded by the DCO.

If the DCO does not agree with the *Athlete's* opinion that all of the equipment available for the selection is unsatisfactory, the DCO shall instruct the *Athlete* to proceed with the Sample Collection Session. If the DCO agrees with the reasons put forward by the *Athlete* that all of the equipment available for the selection is unsatisfactory, the DCO shall terminate the collection of the *Athlete's* urine *Sample* and this shall be recorded by the DCO.

C.4.5 The *Athlete* shall retain control of the collection vessel and any *Sample* provided until the *Sample* is sealed, unless assistance is required by an *Athlete's* disability as provided for in Annex B – Modifications for *Athletes* with disabilities.

C.4.6 The DCO/Chaperone who witnesses the passing of the *Sample* shall be of the same gender as the *Athlete* providing the *Sample*.

C.4.7 The DCO/Chaperone and *Athlete* shall proceed to an area of privacy to collect a *Sample*.

C.4.8 The DCO/Chaperone shall witness the *Sample* leaving the *Athlete's* body and record the witnessing in writing.

C.4.9 The DCO shall use the relevant laboratory's specifications to verify, in full view of the *Athlete*, that the volume of the urine *Sample* satisfies the laboratory's requirements for analysis.

C.4.10 Where the volume of urine is insufficient, the DCO shall conduct a partial *Sample* collection procedure as prescribed in Annex E – Urine *Samples* – insufficient volume.

C.4.11 The DCO shall instruct the *Athlete* to select a *Sample* collection kit containing A and B bottles in accordance with C.4.4.

C.4.12 Once a *Sample* collection kit has been selected, the DCO and the *Athlete* shall check that all code numbers match and that this code number is recorded accurately by the DCO.

If the *Athlete* or DCO finds that the numbers are not the same, the DCO shall instruct the *Athlete* to choose another kit in accordance with C.4.4. The DCO shall record the matter.

C.4.13 The *Athlete* shall pour the relevant laboratory's prescribed minimum volume of urine into the B bottle, and then fill the A bottle as much as possible. The *Athlete* shall then fill the B bottle as much as possible with the remaining urine. The *Athlete* shall ensure that a small amount of urine is left in the collection vessel.

C.4.14 The *Athlete* shall seal the bottles as directed by the DCO. The DCO shall check, in full view of the *Athlete*, that the bottles have been properly sealed.

C.4.15 The DCO shall use the relevant laboratory's guidelines for pH and specific gravity to test the residual urine in the collection vessel to determine if the *Sample* is likely to meet the laboratory guidelines. If it is

not, then the DCO shall follow Annex F - Urine *Samples* - *Samples* that do not meet laboratory pH and specific gravity guidelines.

C.4.16 The DCO shall ensure any residual urine that will not be sent for analysis is discarded in full view of the *Athlete*.

Annex D - Collection of blood Samples

D.1 Objective

To collect an *Athlete's* blood *Sample* in a manner that ensures:

- a) The health and safety of the *Athlete* and Sample Collection Personnel are not compromised;
- b) The *Sample* is of a quality and quantity that meets the relevant analytical guidelines;
- c) The *Sample* is clearly and accurately identified; and
- d) The *Sample* is securely sealed.

D.2 Scope

The collection of a blood *Sample* begins with ensuring the *Athlete* is informed of the *Sample* collection requirements and ends with properly storing the *Sample* prior to dispatch for analysis at the WADA accredited laboratory or as otherwise approved by WADA.

D.3 Responsibility

D.3.1 The DCO has the responsibility for ensuring that:

- a) Each *Sample* is properly collected, identified and sealed; and
- b) All *Samples* have been properly stored and dispatched in accordance with the relevant analytical guidelines.

D.3.2 The Blood Collection Official has the responsibility for collecting the blood *Sample*, answering related questions during the provision of the *Sample*, and proper disposal of used blood sampling equipment not required for completing the Sample Collection Session.

D.4 Requirements

D.4.1 Procedures involving blood shall be consistent with relevant principles of internationally recognised standard precautions in health care settings.

D.4.2 Blood Sample Collection Equipment shall consist of, either an A sample tube, or an A sample tube and a B sample tube. If the sample collection consists solely of blood then a B sample shall be collected and used as a confirmation if required.

D.4.3 The DCO shall ensure that the *Athlete* is informed of the requirements of the *Sample* collection, including any modifications as provided for in Annex B – Modifications for *Athletes* with disabilities.

D.4.4 The DCO/Chaperone and *Athlete* shall proceed to the area where the *Sample* will be provided.

D.4.5 The DCO shall ensure the *Athlete* is offered comfortable conditions including being in a relaxed position for at least 10 minutes prior to providing a *Sample*.

D.4.6 The DCO shall instruct the *Athlete* to select the *Sample* collection kit/s required for collecting the *Sample* and to check that the selected equipment has not been tampered with and the seals are intact. If the *Athlete* is not satisfied with a selected kit, he/she may select another. If the *Athlete* is not satisfied with any kits and no others are available, this shall be recorded by the DCO.

If the DCO does not agree with the *Athlete's* opinion that all of the available kits are unsatisfactory, the DCO shall instruct the *Athlete* to proceed with the *Sample Collection Session*.

If the DCO agrees with the reasons put forward by the *Athlete* that all available kits are unsatisfactory, the DCO shall terminate the collection of the *Athlete's* blood *Sample* and this shall be recorded by the DCO.

D.4.7 When a *Sample* collection kit has been selected, the DCO and the *Athlete* shall check that all code numbers match and that this code number is recorded accurately by the DCO.

If the *Athlete* or DCO finds that the numbers are not the same, the DCO shall instruct the *Athlete* to choose another kit in accordance with D.4.5. The DCO shall record the matter.

D.4.8 The Blood Collection Official shall clean the skin with a sterile disinfectant wipe or swab in a location unlikely to adversely affect the *Athlete* or his/her performance and, if required, apply a tourniquet. The Blood Collection Official shall take the blood *Sample* from a superficial vein into the final collection container. The tourniquet, if applied, shall be immediately removed after the venipuncture has been made.

D.4.9 The amount of blood removed shall be adequate to satisfy the relevant analytical requirements for the *Sample* analysis to be performed.

D.4.10 If the amount of blood that can be removed from the *Athlete* at the first attempt is insufficient, the Blood Collection Official shall repeat the procedure. Maximum attempts shall be three. Should all attempts fail, then the Blood Collection Official shall inform the DCO. The DCO shall terminate the collection of the blood *Sample* and record this and the reasons for terminating the collection.

D.4.11 The Blood Collection Official shall apply a dressing to the puncture site/s.

D.4.12 The Blood Collection Official shall dispose of used blood sampling equipment not required for completing the *Sample Collection Session*.

D.4.13 The *Athlete* shall seal his/her *Sample* into the *Sample* collection kit as directed by the DCO. In full view of the *Athlete*, the DCO shall check that the sealing is satisfactory.

D.4.14 The sealed *Sample* shall be kept at a cool, but not freezing, temperature prior to analysis at the Doping Control Station or dispatch for analysis at the *WADA* accredited laboratory or as otherwise approved by *WADA*.

Annex E - Urine *Samples* - Insufficient volume

E.1 Objective

To ensure that where an insufficient volume of urine is provided, appropriate procedures are followed.

E.2 Scope

The procedure begins with informing the *Athlete* that the *Sample* is of insufficient volume and ends with the provision of a *Sample* of sufficient volume.

E.3 Responsibility

The DCO has the responsibility for declaring the *Sample* volume insufficient and for collecting the additional *Sample/s* to obtain a combined *Sample* of sufficient volume.

E.4 Requirements

E.4.1 If the *Sample* collected is of insufficient volume, the DCO shall inform the *Athlete* that a further *Sample* shall be collected to meet the relevant laboratory's volume requirements.

E.4.2 The DCO shall instruct the *Athlete* to select partial *Sample Collection Equipment* in accordance with C.4.4.

E.4.3 The DCO shall then instruct the *Athlete* to open the relevant equipment, pour the insufficient *Sample* into the container and seal it as directed by the DCO. The DCO shall check, in full view of the *Athlete*, that the container has been properly sealed.

E.4.4 The DCO and the *Athlete* shall check that the equipment code number, and the volume and identity of the insufficient *Sample* are recorded accurately by the DCO. Either the *Athlete* or the DCO shall retain control of the sealed partial *Sample*.

E.4.5 While waiting to provide an additional *Sample*, the *Athlete* shall remain under continuous observation and be given the opportunity to hydrate.

E.4.6 When the *Athlete* is able to provide an additional *Sample*, the procedures for collection of the *Sample* shall be repeated as prescribed in Annex C – Collection of urine *Samples* until a sufficient volume of urine will be provided by combining the initial and additional *Sample/s*.

E.4.7 When the DCO is satisfied that a sufficient volume of urine has been provided, the DCO and *Athlete* shall check the integrity of the seal/s on the partial *Sample* container/s containing the previously provided insufficient *Sample/s*. Any irregularity with the integrity of the seal/s will

be recorded by the DCO and investigated according to Annex A – Investigating a possible failure to comply.

E.4.8 The DCO shall then direct the *Athlete* to break the seal/s and combine the *Samples*, ensuring that additional *Samples* are added sequentially to the first *Sample* collected until the required volume is met.

E.4.9 The DCO and *Athlete* shall then continue with C.4.11.

Annex F - Urine Samples - Samples that do not meet laboratory pH or specific gravity guidelines

F.1 Objective

To ensure that when the urine *Sample* does not meet the contracted laboratory pH or specific gravity guidelines, appropriate procedures are followed.

F.2 Scope

The procedure begins with the DCO informing the *Athlete* that a further *Sample* is required and ends with the collection of a *Sample* that meets laboratory pH and specific gravity guidelines or appropriate follow-up action by the *ADO* if required.

F.3 Responsibility

The *ADO* is responsible for establishing criteria for the number of additional *Samples* to be collected at the *Athlete's Sample Collection Session*. If the additional *Sample/s* collected do not meet the relevant laboratory's guidelines for analysis, the *ADO* is responsible for scheduling a new *Sample Collection Session* for the *Athlete* and, if required, taking subsequent appropriate action.

The DCO is responsible for collecting additional *Sample/s* in accordance with the *ADO's* criteria.

F.4 Requirements

F.4.1 The *ADO* shall establish criteria for the number of additional *Samples* to be collected by the DCO when the DCO determines that an *Athlete's Sample* is unlikely to meet the relevant laboratory's pH or specific gravity guidelines.

F.4.2 The DCO shall inform the *Athlete* that he/she is required to provide a further *Sample*.

F.4.3 While waiting to provide an additional *Sample*, the *Athlete* shall remain under continuous observation.

F.4.4 When the *Athlete* is able to provide an additional *Sample*, the DCO shall repeat the procedures for collection of the *Sample* as prescribed in Annex C – Collection of urine *Sample* and in accordance with the *ADO's* criteria for the number of additional *Samples* to be collected as established in F.4.1..

F.4.5 The DCO shall record that the *Samples* collected belong to a single *Athlete* and the order in which the *Samples* were provided.

F.4.6 The DCO shall then continue with C.4.16.

F.4.7 If it is determined by the relevant laboratory that all of the *Athlete's Samples* do not meet the laboratory's pH and specific gravity requirements for analysis and this is not related to natural causes, the ADO shall schedule another Sample Collection Session for the *Athlete* as *Target Testing* as soon as possible.

F.4.8 If the *Target Testing Sample Collection Session* also results in *Samples* that do not meet the laboratory's pH and/or specific gravity requirements for analysis, the ADO shall investigate a possible anti-doping rule violation.

Annex G - Sample Collection Personnel Requirements

G.1 Objective

To ensure that Sample Collection Personnel have no conflict of interest and have adequate qualifications and experience to conduct *Sample* collection sessions.

G.2 Scope

Sample Collection Personnel requirements starts with the development of the necessary competencies for Sample Collection Personnel and ends with the provision of identifiable accreditation.

G.3 Responsibility

The *ADO* has the responsibility for all activities defined in this Annex G.

G.4 Requirements - Qualifications and Training

G.4.1 The *ADO* shall determine the necessary competence and qualification requirements for the positions of Doping Control Officer, Chaperone and Blood Collection Official. The *ADO* shall develop duty statements for all Sample Collection Personnel that outline their respective responsibilities. As a minimum:

- a) Sample Collection Personnel shall be of adult age.
- b) Blood Collection Officials shall have adequate qualifications and practical skills required to perform blood collection from a vein.

G.4.2 The *ADO* shall ensure that Sample Collection Personnel that have an interest in the outcome of the collection or testing of a *Sample* from any *Athlete* who might provide a *Sample* at a session are not appointed to that *Sample* collection session. Sample Collection Personnel are deemed to have an interest in the collection of a *Sample* if they are:

- a) Involved in the planning of the sport for which testing is being conducted; or
- b) Related to, or involved in the personal affairs of any *Athlete* who might provide a *Sample* at that session.

G.4.3 The *ADO* shall establish a system that ensures that Sample Collection Personnel are adequately qualified and trained to carry out their duties.

G.4.4 The training program for Chaperones and Blood Collection Officers as a minimum shall include studies of all relevant requirements of the testing process and familiarization of relevant standard precautions in healthcare settings.

G.4.5 The training program for Doping Control Officers as a minimum shall include:

- a) Comprehensive theoretical training in different types of testing activities relevant to the Doping Control Officer position;
- b) One observation of all doping control activities related to requirements in this standard, preferably on site;
- c) The satisfactory performance of one complete *Sample* collection on site under observation by a qualified Doping Control Officer or similar. The requirement related to actual passing of *Sample* shall not be included in the on site observations.

G.4.6 The ADO shall maintain records of education, training, skills and experience.

G.5 Requirements - Accreditation, re-accreditation and delegation

G.5.1 The ADO shall establish a system for accrediting and re-accrediting Sample Collection Personnel.

G.5.2 The ADO shall ensure that Sample Collection Personnel have completed the training program and are familiar with the requirements in this testing standard before granting accreditation.

G.5.3 Accreditation shall only be valid for a maximum of two years. Sample Collection Personnel shall be required to repeat a full training program if they have not participated in *Sample* collection activities within the year prior to re-accreditation.

G.5.4 Only Sample Collection Personnel that have an accreditation recognised by the ADO shall be authorised by the ADO to conduct *Sample* collection activities on behalf of the ADO.

G.5.5 Doping Control Officers may personally perform any activities involved in the Sample Collection Session, with the exception of blood collection unless particularly qualified, or they may direct a Chaperone to perform specified activities that fall within the scope of the Chaperone's authorised duties.

World Anti-Doping Program

GUIDELINES FOR URINE SAMPLE COLLECTION

Version 4
June 2004

WADA STANDARDS AND HARMONIZATION – GUIDELINE FOR URINE SAMPLE COLLECTION

| 6.6 <i>Athletes who self-catheterize</i> | 20 |

Appendix 1 Chaperone Training Guidelines

1. Objective

This guideline expands upon the International Standard for Testing and details the recommended process for the collection of urine for doping control purposes, both In-Competition and Out-of-Competition. The guideline includes on-site preparation, sample collection and post-test administration.

With the exception of those mandatory areas which are part of the World Anti-Doping Program, the processes outlined in this document are not mandatory, but are aimed at assisting *Anti-Doping Organizations* in the development of systems and protocols for urine sample collection. The method of sample collection may vary from these recommendations in some circumstances; however, minimum standards should apply to ensure that the integrity of the sample is maintained.

2. Scope

This Guideline begins with the arrival of *Sample Collection Personnel* at the *Doping Control Station*, and ends with the dispatch of the urine sample to the laboratory.

3. Responsibility

3.1. *Doping Control Officer (DCO)*

(One lead/senior DCO shall take responsibility for sample collection services)

- Organize and brief *Sample Collection Personnel*.
- Ensure that Chaperones are trained in carrying out relevant activities.
- Liaise with sport representatives, if relevant.
- Organize equipment, including all relevant documentation.
- Assess and organize the facilities.
- Arrange or perform notification and escorting of *Athletes*.
- Ensure that the *Athlete's* rights and responsibilities are explained.
- Explain, or arrange explanation of, the process for urine sample collection to *Athletes* and Athlete Representatives, as necessary.
- Witness, or arrange the witnessing of, sample provision.
- Co-ordinate collection of accompanying blood sample if necessary.
- Complete, or arrange completion of, and verify, the relevant paperwork.
- Verify the chain of custody.
- Organize courier services, if necessary.

3.2. *Chaperone*

- Notify the *Athlete* in person as instructed by the DCO.
- Escort the *Athlete* from notification until arrival at the *Doping Control Station*.
- If appropriately trained and authorized (see Appendix 1), act as the Witness for sample provision as instructed by the DCO and complete the relevant section of the doping control documentation as instructed by the DCO.

- NOTE: Some *Anti-Doping Organizations* prefer that Chaperones do not witness sample provision but conduct *Athlete* notification only. These Guidelines allow for both these scenarios.

3.3. *Athlete*

- Request the presence of an Athlete Representative, if desired.
- Report for doping control as soon as possible, and within the specified time frame.
- Be escorted from notification to sample provision.
- Be responsible for any food or beverage consumed prior to sample provision.
- Be familiar with the sample collection process.
- Be responsible at all times for his/her own sample(s) from provision to final sealing.
- Observe the procedure and ensure there are no irregularities.
- Declare any medications as specified on the doping control documentation.
- Provide a TUE certificate if applicable.
- Make comments relating to the sample collection process on the doping control documentation, if applicable.
- Sign documentation as requested by the DCO.

3.4. Athlete Representative (*presence optional, at Athlete's request*)

- Accompany the *Athlete* during notification.
- Accompany the *Athlete* to the *Doping Control Station*.
- Assist in the selection of equipment and the sealing process where asked to do so by the *Athlete*.
- Assist the *Athlete* in the completion of paperwork where asked to do so by the *Athlete*.
- Be familiar with the sample collection process.
- Observe the sample collection process and ensure there are no irregularities.
- Sign documentation as requested by the DCO.

4. Definitions

"*Anti-Doping Organization*" means a Signatory (of the World Anti-Doping Code) that is responsible for adopting rules, for initiating, implementing or enforcing any part of the doping control process. This includes, for example, the International Olympic Committee, the International Paralympic Committee, or other major event organizations that conduct testing at their events, WADA, International Federations, and National Anti-Doping Organizations.

'*Athlete*' means for purposes of doping control, any person who participates in sport at the international level (as defined by each International Federation), or national level (as defined by each National Anti-Doping Organization) and any additional person who participates in sport at the lower level if designated by the person's National Anti-Doping Organization. For purposes of anti-doping information and education, any person who participates in sport under the authority of any signatory, government, or other sports organization accepting the Code.

'Athlete Representative' means a person designated by the *Athlete* to assist with the verification of the sample collection procedure, (not including the passing of the sample). This person may be a member of the *Athlete's* support personnel, such as a coach or team doctor, a family member, or other.

'Chaperone' means an official who is trained and authorized by the ADO to carry out specific duties including notification of the *Athlete* selected for sample collection, escorting and observing the *Athlete* until arrival at the *Doping Control Station*, and/or witnessing and verifying the provision of the sample where training qualifies him/her to do so.

'Doping Control Officer' means an official who has been trained and authorized by the ADO with delegated responsibility for the on-site management of a sample collection session.

'Doping Control Station' means the location where the *urine sample collection session* will be conducted.

'In-Competition' means for purposes of differentiating between *In Competition* and *Out of Competition* Testing, unless provided otherwise in the rules of an ADO, an *In-Competition* test is a test where an *Athlete* is selected for testing in connection with a specific competition.

'Minor' means a natural person who has not reached the age of maturity as established by the applicable laws of his or her country of residence.

'Out of Competition' means any doping control which is not *In-Competition*.

'No-Advance-Notice' means a doping control which takes place with no advance warning to the *Athlete*, and where the *Athlete* is continuously Chaperoned from the moment of notification through sample provision.

'TUE' means a Therapeutic Use Exemption (see International Standard for Therapeutic Use Exemptions).

'Sample Collection Personnel' is a collective term for qualified officials authorized by the ADO who may carry out or assist with duties during the sample collection session.

'Urine Sample Collection Session' means the sequential activities that directly involve the *Athlete* from notification until the *Athlete* leaves the *Doping Control Station* having provided his/her samples(s).

'Weighted Selection' means a ranking method of selecting *Athletes* using criteria where the ranking is based on the potential risk of doping and possible doping patterns.

'Witness' means the member of *Sample Collection Personnel* who observes the passing of the sample by the *Athlete* in accordance with the procedures for observation.

5. Protocol for the Urine Sample Collection Session

The protocol for the *urine sample collection session* is divided into the following steps:

5.1. Brief personnel on roles and responsibilities

- 5.1.1. The Lead DCO shall brief the *Sample Collection Personnel* on their roles and responsibilities prior to or upon arrival at the *Doping Control Station*. This will include *Athlete* notification, escorting, urine sample collection, and related blood sample collection if applicable.
- 5.1.2. In the case of a team which includes Chaperones with no experience, the DCO shall train the Chaperones on-site. Such training shall include the requirements for notification, escorting and witnessing sample provision, as well as confidentiality obligations (see Appendix 1 for Chaperone Training Guidelines).
- 5.1.3. The DCO shall provide required documentation such as proof of authority to conduct sample collection, to the *Sample Collection Personnel* if applicable.

5.2 Assess the facilities

- 5.2.1 The minimum requirements to be met to enable use of a facility as a *Doping Control Station* are privacy and sole-use. If the facility does not offer the *Athlete* privacy, and/or is intended to be used for purposes other than doping control whilst sample collection is being carried out, the Lead DCO may decide not to proceed with testing. The reasons for such a decision must be documented.
- 5.2.2 For *In-Competition* testing, where possible, the *Doping Control Station* should meet the following criteria:
 - Be solely reserved for doping control purposes
 - Maintain *athlete* privacy and confidentiality
 - Be accessible only to authorized personnel
 - Be secure enough to store sample collection equipment
 - Be comprised of a waiting area with chairs and a separate administration area with a table and chairs for completion of paperwork. There should be adjoining toilet facilities for sample provision, which should ideally consist of cubicles large enough for the Witness and the *Athlete*.
 - Include facilities to allow the *Athlete* to wash his/her hands.
 - Be large enough to accommodate the number of *Athletes*, Athlete Representatives and *Sample Collection Personnel* who will occupy the area
 - Be suitably located in relation to the field of play or other location where *Athletes* will be notified.

- 5.2.3 For *Out-of-Competition* testing, the facilities used should, where possible, provide a suitable environment for waiting and administration, and afford the *Athlete* privacy.

NOTE: Although the term '*Doping Control Station*' is also used for *Out-of-Competition* testing, this facility might be an *athlete's* home or a hotel room, rather than an officially designated facility for doping control.

- 5.2.4 The *Doping Control Station* at an event should also contain a selection of sealed, non-alcoholic, caffeine-free drinks for *Athletes*.
- 5.2.5 Access to the *Doping Control Station* is restricted to the *Athlete*, the Athlete Representative, an interpreter if required, and *Sample Collection Personnel*, unless otherwise agreed by the Lead DCO. Additional personnel requesting access may include an IF representative, an ADO observer, an auditor or a WADA Independent Observer. These personnel shall have adequate authorization available for the Lead DCO to review upon arrival at the *Doping Control Station*.
- 5.2.6 The Lead DCO may wish to assign a member of the sample collection team to monitor access to the *Doping Control Station*, and ensure that only authorized persons are admitted.
- 5.2.7 Members of the media must not be allowed to enter the *Doping Control Station* at any time.
- 5.3 *Prepare the necessary equipment*
- 5.3.1 The DCO shall ensure equipment supplies are adequate for the sample collection session. The type of equipment may vary but, as a guideline, will include:

- Sealed, sterile urine collection vessels.
- Partial sample kits.
- Equipment for measuring pH (if required), and specific gravity.
- Sealed, tamper-evident containers for A and B samples.
- Sealed, tamper-evident transport containers (if applicable).
- Secure transport bags.
- Disposable gloves (optional).
- Soap or hand wash
- Paper towels
- Garbage bin or similar for disposal
- Individually sealed, non-caffeinated and non-alcoholic beverages
- All doping control documentation, including doping control forms, *Athlete* notification forms, supplementary report forms, chain of custody forms, etc.

5.3.2 Any sample collection equipment systems used shall meet the following minimum criteria:

- Have a unique numbering system incorporated into all containers in which the *Athlete's* sample is sealed.
- Have a sealing system that is tamper-evident.
- Ensure the identity of the *Athlete* is not evident from the equipment itself.
- Ensure that all equipment is clean and sealed prior to use.

5.4 *Athlete Selection*

5.4.1 The DCO will select *athletes* according to the selection policy indicated by the ADO. This may include one or all of the following: target testing (named *athletes* or categories), *weighted* selection and random selection.

5.4.2 In the case of random selection, the ADO/DCO may choose to use one of the following selection criteria. The criteria chosen shall be appropriate for the sport, e.g:

- Finishing position
- Vest/jersey number
- Entry number
- Lane number
- Any other fair and transparent criteria for selection

5.4.3 Once the criteria has been determined, the actual selection method may be one of the following:

- Numbered cards placed face-down on a table
- Random draw of numbers (or names) from a closed container such as a cloth bag
- Use of an electronic random number generator
- Any other fair and transparent method of selection

In order to provide transparency and accountability, random selection made in the field may be witnessed by a coach or sporting official, or can be shown to the selected athlete if requested. For example a signature on the back of numbered cards.

5.4.4 Following the selection of the *Athlete*, the Lead DCO shall ensure that selection decisions are disclosed on a need-to-know basis only to ensure that testing is *No-Advance Notice*.

5.5 *Athlete notification*

5.5.1 The DCO/Chaperone shall establish the location of the selected *Athlete*, and plan the approach and timing of notification, taking into account any specific circumstances such as the competition/training schedule, and such that the notification will be carried out as *No-Advance-Notice* notification.

- 5.5.2 The DCO/Chaperone shall identify him/herself and shall show the *Athlete* the official card/document naming the ADO which has granted the authority to test. Additional identification proving affiliation to the authorized sample collection authority shall also be provided, if this authority is not the ADO which authorized the test. DCO identification documents shall include name, photograph, and the documents' expiry date. Chaperone identification documents shall ideally also include name, photograph, and the documents' expiry date, and as a minimum shall comprise a dated document naming them as an authorized member of the sample collection team, which they shall show to the athlete in conjunction with a piece of photo ID.
- 5.5.3 The DCO/Chaperone shall, at a minimum, verbally confirm the *Athlete's* identity. If the *Athlete* is carrying photo ID, this may be checked at this stage. An *Athlete's* inability to provide photo ID shall not invalidate a test. Formal identification can be established by starting number, accreditation, third party witness, if the *Athlete* is known to the DCO/Chaperone, or other viable method. If the *Athlete's* identity is unknown and can not be established in any manner, the DCO must contact the ADO for further instructions.
- 5.5.4 The DCO/Chaperone shall show the *Athlete* the notification form (which may be part of the doping control form), and notify the *Athlete* of his/her selection for testing, the authority under which sample collection is to be conducted, and the requirement to provide a urine (and blood, if applicable) sample, and shall inform the *Athlete* of the following rights and responsibilities:
- a) For all types of testing
 - The right to have a representative and, if required, an interpreter present.
 - The right to ask for additional information about the sample collection process
 - The possible consequence of an anti-doping rule violation for failing to submit to sample collection.
 - The requirement to remain in sight of the designated DCO/Chaperone until completion of the sample collection procedure.
 - The requirement to bring satisfactory identification to the *Doping Control Station* if this has not already been provided.
 - b) For the purpose of *In-Competition Testing*
 - The requirement to report to the *Doping Control Station* as soon as possible and not later than 60 minutes from notification.
 - The DCO shall consider reasonable requests to delay the reporting time, if a Chaperone is available, to enable the *Athlete* to complete one or more of the following:
 - locate a representative and/or interpreter
 - warm down
 - attend a medal ceremony
 - participate in further events

- fulfill media commitments
 - receive treatment for injury
 - any other reason accepted by the DCO
- The DCO shall document reasons for any delay that may require further investigation by the ADO.
- c) For the purpose of *Out of Competition Testing*
- The requirement to report to the doping control station and commence sample provision as soon as possible. The DCO shall consider requests to delay reporting, if a Chaperone is available, to enable the *Athlete* to complete one or more of the following:
 - locate a representative, if available
 - complete a training session
 - receive treatment for injury
 - any other reason accepted by the DCO
 - The DCO shall document reasons for any delay that may require further investigation by the ADO.
- 5.5.5 If a selected *athlete* is not located based on available information, the DCO shall attempt to locate the *athlete* by other means, but ensure that *No-Advance-Notice* notification is used as a notification method. The DCO shall notify the ADO for further instructions if the *athlete* is not located. (See WADA's No-Advance Notice Testing Guidelines).
- 5.5.6. The DCO shall report any decision to the ADO if an unexpected situation arises requiring the notification to become advance notice.
- 5.5.7. The *Athlete* shall read and sign the *Athlete* notification form or doping control form as directed by the DCO/Chaperone.
- 5.5.8. If an *Athlete* copy of the official notification record exists, this will be given to the *Athlete*.
- 5.5.9 If the *Athlete* refuses to sign that he/she has been notified, or evades notification, the DCO/Chaperone shall make all reasonable attempts to persuade the *Athlete* to comply, including informing the *Athlete* again that failure to comply may result in sanction for an anti-doping rule violation. If the *Athlete* continues to refuse, the Chaperone must report this to the Lead DCO immediately, and the DCO shall attempt to notify the *Athlete*. If the *Athlete* still refuses to be notified, the DCO shall document the facts, including the reasons for refusal given by the *Athlete*. The DCO shall endeavor to obtain witness signatures to confirm the *Athlete's* refusal, and shall contact the ADO for further instructions as soon as possible.

5.6 *Escorting the Athlete to the Doping Control Station.*

- 5.6.1 The DCO/Chaperone shall ensure that the *Athlete* is escorted from the place of notification to the *Doping Control Station* under constant supervision.
- 5.6.2 The DCO/Chaperone shall discourage the *Athlete* from taking a bath or shower, and shall ensure he/she does not urinate prior to reporting at the *Doping Control Station*. The first urine sample post notification shall be collected.
- 5.6.3 The DCO/Chaperone can not prevent the *Athlete* eating or drinking products of their choice, but shall recommend that the *Athlete* chooses from a selection of individually sealed, non-caffeinated and non-alcoholic beverages in order to hydrate. The DCO/Chaperone shall not handle food or drink items for the *Athlete*.
- 5.6.4 The DCO/Chaperone shall escort the *Athlete* at all times until the sample collection procedures have been completed, or shall ensure that another DCO/Chaperone has taken over escorting the *Athlete*.
- 5.6.5 The Chaperone shall inform the Lead DCO as soon as practical without leaving the *Athlete* unattended, and ensuring discretion, of any irregularities in notification and/or during the observation period. Irregularities shall be documented by the Lead DCO if relevant.

NOTE: The ADO is responsible for establishing guidelines for what constitutes suspicious *athlete* behavior – examples might be; evading observation, ingesting an unidentified substance, a distressed call to a coach or other unusual behavior.

- 5.6.6 If an *Athlete* notified of an advance notice sample collection does not report to the *Doping Control Station* at the designated time, the DCO shall use his/her judgement as to whether to attempt to contact the *athlete*. At a minimum, the DCO shall wait 30 minutes after the appointed time before departing.
- 5.6.7 If an *Athlete* reports to the *Doping Control Station* after the minimum waiting time, and prior to the DCO's departure, the Lead DCO shall decide whether to process a possible failure to comply. Where possible, the DCO shall proceed with collecting a sample, and shall document the details of the delay.

NOTE: *No-Advance-Notice* is the preferred method of doping control. The situation described in 5.6.6 and 5.6.7 shall be in exceptional circumstances only; an *Athlete* should ideally be escorted at all times, and the escorting DCO/Chaperone shall ensure that the *Athlete* reports for doping control as quickly as possible, taking into account the provisions of 5.5.4.

5.7 *Arrival at the Doping Control Station*

- 5.7.1 The *Athlete* arrives at the *Doping Control Station* with a DCO/Chaperone and, if requested, an Athlete Representative and/or interpreter. At this time, the *Athlete* should present photo ID to the DCO. An *Athlete's* inability to provide

photo ID shall not invalidate a test. Alternative methods of *Athlete* identification are outlined in 5.5.3.

- 5.7.2 An entry and exit log shall be maintained to record the names of the persons entering facility, their position, and the times of arrival and departure.
- 5.7.3 The *Athlete* shall be provided with the opportunity to hydrate.
- 5.7.4 If the *Athlete* is providing a blood sample at the same session, the DCO may request that the *Athlete* provide the blood sample first.
- 5.7.5 Irrespective of the testing type or escorting requirements prior to the time of arrival, once the *athlete* has arrived at the *Doping Control Station* he/she must be under observation at all times until sample collection is completed
- 5.7.6 The *Athlete* may request to leave the *Doping Control Station* for a time, for reasons defined in 5.5.4. The *Athlete* must be escorted continuously at such times, and the purpose of leaving, agreed time of return, and actual time of return shall be documented by the Lead DCO. If a Chaperone is not available, the DCO shall ask the *Athlete* to remain in the *Doping Control Station*. If an *Athlete* insists on leaving the *Doping Control Station*, the circumstances shall be documented by the Lead DCO.
- 5.7.7 Before sample collection, the DCO shall ask the *Athlete* whether they have been tested before, and whether they require an explanation of the collection procedure.
- 5.7.8 If the *Athlete* has not been tested before, or requests an explanation of the procedure, the DCO shall explain the sample collection procedure to the *Athlete*.
- 5.7.9 As a minimum, the DCO shall ensure the *Athlete* is informed of his/her rights and responsibilities

5.8 *Selection of the sample collection vessel*

- 5.8.1 The *Athlete* shall be given a choice of sample collection vessels, from which they will be asked to choose one. It is recommended that there are at least 3 sample collection vessels from which to choose.
- 5.8.2 The *Athlete* and DCO shall check that the equipment is clean and intact. If either the *Athlete* or DCO is not satisfied with the equipment, the *Athlete* shall make another selection.
- 5.8.3 If the *Athlete* is not satisfied with any of the equipment, and the DCO does not agree with the *Athlete's* opinion that all of the available equipment is unsatisfactory, the DCO shall instruct the *Athlete* to proceed with the sample

collection session and the *Athlete's* views must be recorded on the doping control documentation by the DCO.

- 5.8.4 If both the DCO and the *Athlete* agree that none of the equipment is satisfactory, the DCO shall terminate sample collection, and record the reasons.
- 5.8.5 From this point, the sample collection vessel shall be handled only by the *Athlete* unless the *Athlete* authorizes the DCO/Chaperone or the *Athlete* Representative to handle the vessel on his/her behalf. Such authorization must be documented.

5.9 Sample Provision

- 5.9.1 The Witness (DCO or Chaperone) shall escort the *Athlete* to the toilet facility. The *Athlete* will carry his/her own sample collection vessel.
- 5.9.2 The Witness shall be of the same gender as the *Athlete* providing the sample.
- 5.9.3 The *Athlete* shall be encouraged to wash his/her hands before providing a sample.
- 5.9.4 Once in the toilet facility the *Athlete* must remove all clothing between the waist and mid-thigh, in order that the Witness has an unobstructed view of sample provision. Sleeves should be rolled up so that the *Athlete's* arms and hands are also clearly visible.
- 5.9.5 The Witness shall directly observe the *Athlete* provide the urine sample, adjusting his/her position so as to have a clear view of the sample leaving the *Athlete's* body.
- 5.9.6 The volume of urine collected should be that specified by the relevant laboratory.

NOTE: As a guideline, it is suggested that between 75ml and 100ml of urine be collected, depending on laboratory requirements. For EPO analysis, the recommended minimum is 100ml. However, the *Athlete* should be encouraged to fill the collection vessel.

- 5.9.7 Once a urine sample which satisfies the volume requirements has been collected, or the *Athlete* has provided a partial sample and is unable to provide any more urine at this time, the Witness shall escort the *Athlete*, who shall carry his/her own sample, back to the administration area.
- 5.9.8 If an *Athlete* wishes to wash his/her hands after passing the sample, the sample should at this time be placed in a safe and secure location, in full view of both the *Athlete* and the Witness.

- 5.9.9 If the Witness observes any unusual behavior by the *Athlete* while witnessing the passing of the sample, this should be reported to the Lead DCO as soon as possible, and documented.
- 5.9.10 The Witness shall sign the relevant documentation to verify that he/she witnessed sample provision in accordance with procedures

5.10. Insufficient Volume

- 5.10.1 In the event that an *Athlete* is unable to provide the required volume of urine, the DCO shall follow the procedure for a partial sample.
- 5.10.2 The DCO shall advise the *Athlete* that the partial sample provided shall be secured and a further sample collected.
- 5.10.3 The DCO shall instruct the *Athlete* to select partial sample equipment, as per 5.8. It is recommended that there are at least 3 partial sample kits from which to choose.
- 5.10.4 The DCO shall then instruct the *Athlete* to open the relevant equipment, pour the insufficient sample into the container, and seal it as directed by the DCO. The DCO shall check, in full view of the *Athlete*, that the container has been properly sealed.
- 5.10.5 The DCO and the *Athlete* shall check that the equipment code number and the volume and identity of the insufficient sample are recorded accurately by the DCO. The *Athlete* and DCO may initial or sign the documentation to show they are satisfied with the procedure.
- 5.10.6 The *Athlete* shall return to the waiting area, and remain under observation until ready to provide a further sample.
- 5.10.7 Either the *Athlete* or the DCO shall retain control of the sample. The DCO shall ensure that the sealed partial sample is securely stored (under continuous observation or locked away in a secure area). If the *athlete* retains possession of the sample, it must be placed in a secure area, and must remain under the observation of *sample collection personnel*.
- 5.10.8 When the *Athlete* is ready to provide more urine, the sample provision process shall recommence.
- 5.10.9 To ensure continuity of the process, and for the comfort of the *Athlete*, the Witness shall be the same Witness as for the initial attempt, whenever possible. However, a change of Witness shall in no way affect the integrity of the process.
- 5.10.10 The *Athlete* shall select a new sample collection vessel, and repeat the process as per 5.8.

- 5.10.11 This process shall be repeated until the DCO is satisfied that the *Athlete* has provided the required volume of urine once the initial and additional samples are combined.
- 5.10.12 The DCO shall ask the *Athlete* to inspect their partial sample(s) to ensure that the seals are secure. Any irregularities shall be recorded by the DCO on the doping control documentation or in a separate report to the ADO.
- 5.10.13 The DCO shall then direct the *Athlete* to break the seal of the partial sample container(s) and combine the samples in a new collection vessel, beginning with the first partial sample provided and each subsequent partial sample until the desired volume is reached.
- 5.10.14 Once the required volume of urine has been collected, the DCO and *Athlete* shall proceed to the next stage.

5.11 Dividing and sealing the sample

- 5.11.1 The *Athlete* shall select, from a choice of urine kits, a kit consisting of A and B containers, in which the sample is to be sealed. It is recommended that there are at least 3 urine kits from which to choose.
- 5.11.2 The *Athlete* and DCO shall check that the urine kit is clean and intact. If neither the *Athlete* nor the DCO is satisfied with the urine kit(s), the *Athlete* shall make another selection.
- 5.11.3 If the *Athlete* is not satisfied with any of the urine kits, and the DCO does not agree with the *Athlete's* opinion that all of the available urine kits are unsatisfactory, the DCO shall instruct the *Athlete* to proceed with the sample collection session, and the *Athlete's* views must be recorded on the doping control documentation by the DCO.
- 5.11.4 If both the DCO and the *Athlete* agree that none of the urine kits are satisfactory, the DCO shall terminate the session, and record the reasons.
- 5.11.5 The *Athlete* and the DCO shall check the urine kit to ensure that all the numbers of the A and B containers correspond.
- 5.11.6 If the numbers do not correspond, the DCO shall instruct the *Athlete* to select another kit. The DCO shall document this.
- 5.11.7 The DCO shall record the urine kit numbers and the *Athlete* and the DCO shall check the documentation to ensure that the DCO has accurately recorded the numbers of the A and B containers.
- 5.11.8 The *Athlete* shall pour the required minimum volume of urine into the B container. The recommended amount is 40% of the total.

- 5.11.9 The *Athlete* shall pour the remainder of the urine into the A container. The recommended amount is 60% of the total. The *Athlete* shall then pour any remaining urine into the B container, always leaving a residual amount of urine in the collection vessel.
- 5.11.10 The DCO shall instruct the *Athlete* in the sealing of the A and B containers. Both the DCO and the *Athlete* shall check that the bottles are securely sealed.
- 5.11.11 The DCO shall confirm that the sample meets the requirements for analysis, as specified by the ADO in accordance with the laboratory standards, by testing the residual volume of urine remaining in the collection vessel for specific gravity (greater than or equal to 1.005 if using a refractometer, or 1.010 with lab sticks, or as specified by the relevant laboratory) and, if necessary, pH (between 5 and 7, or as specified by the relevant laboratory). Reagent strips and/or a refractometer may be used.
- 5.11.12 The DCO shall ensure that any residual urine that will not be sent for analysis is discarded in full view of the *Athlete*.

5.12 Samples not meeting laboratory guidelines for analysis

- 5.12.1 If the reading is outside the required range for either specific gravity or, if required, pH, (5.11.11) the DCO shall request collection of additional sample(s), if so required by the ADO.
- 5.12.2 The ADO is responsible for establishing criteria for the number of additional samples to be collected at the session. If the additional samples collected do not meet the relevant laboratory's guidelines for analysis, the ADO is responsible for scheduling a new sample collection session for the *Athlete* and, if required, taking subsequent appropriate action.
- 5.12.3 While waiting to provide an additional sample the *Athlete* shall remain under continuous observation by a DCO/Chaperone.
- 5.12.4 When the *Athlete* is able to provide an additional sample, the DCO shall repeat the procedures for collection of the sample (5.8 to 5.11).
- 5.12.5 Whenever possible, provision of additional samples shall be observed by the same Witness as for the first. However, a change of Witness will not invalidate the sample collection procedure.
- 5.12.6 The Witness shall sign the relevant documentation to verify that he/she witnessed sample provision in accordance with procedures.
- 5.12.7 The DCO shall ensure that samples provided by the same *Athlete* can be linked through the documentation, and that the laboratory is informed which is the

initial sample. All samples shall be sent to the laboratory for analysis with all related paperwork.

5.13 Paperwork

NOTE: see WADA's standardized doping control documentation for an example of suitable documentation. See also the International Standard for Testing, 7.4.5. for minimum requirements.

- 5.13.1 If the *Athlete* provided more than one sample and the Witness was not the same individual that witnessed provision of the first sample, all Witnesses shall sign the doping control form.
- 5.13.2 If the Witness is unable to verify that he/she observed the passing of the sample, or reports unusual behavior by the *Athlete*, the Lead DCO can require the *Athlete* to provide a further sample. This must be documented, and all samples collected sent to the laboratory for analysis.
- 5.13.3 The DCO shall request the *Athlete* to provide information on all medications and/or supplements taken within the time period specified on the doping control form.

NOTE: The recommended period for medication information is 7 days

- 5.13.4 The DCO shall check all information on the form, fill in any incomplete areas in view of the *Athlete*, and sign to confirm that sample collection was conducted in accordance with procedures.
- 5.13.5 The *Athlete* and the Athlete's Representative, if present, shall be invited to check that all information on the form accurately reflects the details of the sample collection session. The *Athlete* shall be invited to complete the comments section of the form if he/she has any concerns or comments regarding the procedure. If there is insufficient space on the form, the *Athlete* shall be invited to complete a supplementary report form.
- 5.13.6 The Athlete's Representative, if present shall sign the Doping Control Form.
- 5.13.7 The *Athlete* and DCO shall then sign the Doping Control Form.
- 5.13.8 The DCO must give a full copy of the form to the *Athlete*.
- 5.13.9 Unless also required to provide a blood sample, the *Athlete* is then free to leave the *Doping Control Station*.

NOTE: If an Athlete is also required to provide a blood sample, and the doping control form records both blood and urine collection, the paperwork will not be fully completed until after collection of both blood and urine samples.

5.14 Sample Storage

- 5.14.1 The Lead DCO has the responsibility for ensuring, in accordance with the ADO criteria for sample storage, that all samples are stored in a manner that protects their identity, integrity and security whilst in the *Doping Control Station*.
- 5.14.2 Samples must not be left unattended, unless they are locked away in a refrigerator or cupboard, for example. Access shall be restricted to authorized personnel.
- 5.14.3 Where possible, samples shall be stored in a cool environment. Warm conditions should be avoided.
- 5.14.4 The DCO shall accurately complete appropriate documentation for each transport bag/container to ensure that the laboratory can verify the contents of the bag/container.
- 5.14.5 The DCO shall follow the ADO's system to ensure that, where required, instructions for the type of analysis to be conducted are provided to the laboratory.
- 5.14.6 The DCO shall complete the laboratory advice form/chain of custody form. The laboratory copy of this form(s) and the laboratory copy of the doping control form shall be placed in the transport bag with the samples, and sealed, preferably in the presence of a second person. Documentation identifying the *Athlete* shall not be included with the samples.
- 5.14.7 If relevant, the DCO shall record the times the transport bag is opened and re-sealed on the laboratory advice form or chain of custody form.
- 5.14.8 The DCO shall keep the samples secured and under his or her control until they are passed to the courier.
- 5.14.9 All documentation relevant to the testing session shall be forwarded to the ADO by the approved method as soon as possible after sample collection.

5.15 Transport of Samples

- 5.15.1 Samples shall be shipped to the WADA accredited laboratory as soon as practical, and wherever possible on the day of collection.
- 5.15.2 Samples may be taken directly to the laboratory by the DCO, or handed over to a third party for transportation. This third party must document the chain of custody of the samples. If an approved courier company is used to transport the samples, the DCO shall record the waybill number.

5.16 Hand-over of Samples to the laboratory

- 5.16.1 Laboratories are required to document receipt and the subsequent chain of custody of samples. Samples are reviewed for evidence of tampering or damage, and stored in appropriate conditions in accordance with the International Standard for Laboratories.

6 Modifications for Minors and Athletes with a Disability

Minors, or *Athletes* with specific types of disability may require modifications to the sample collection procedure. The modifications outlined below do not affect the integrity of the sample collection process.

The ADO has responsibility for ensuring, when possible, that the Lead DCO has any information and specialised sample collection equipment necessary to conduct a sample collection session with an *Athlete* with a disability requiring assistance during sample provision. The DCO shall have the authority to make modifications as the situation requires, in accordance with these guidelines.

In some cases, with the agreement of the Lead DCO, the *Athlete* may designate the Athlete Representative, or the DCO/Chaperone to assist with the sample collection process.

Any modifications made to the standard sample collection procedure shall be documented by the Lead DCO.

Modifications may be introduced in the case of the following *Athletes*:

6.2 *Minors*

- 6.2.1 *Minors* may, at their request, be accompanied by an Athlete Representative at all times during the sample collection procedure, including in the toilet area. However, the representative shall not witness the passing of the sample, unless requested to do so by the *Athlete*. The objective is to ensure that the Witness is observing sample provision correctly
- 6.2.2 The Athlete Representative or the DCO shall explain the doping control documentation to the *Athlete*, if necessary.
- 6.2.3 *Minors* must be accompanied for the verification of procedure (signing of the doping control form), and the Athlete Representative shall sign in addition to the *Athlete*.

6.3 *Athletes with restricted mobility/ restricted manual dexterity*

- 6.3.1 *Athletes* may ask the Athlete Representative or the DCO/Chaperone to assist them with mobility, when handling equipment, splitting the sample, or completing paperwork.
- 6.3.2 *Athletes* with Cerebral Palsy and/or significant lack of co-ordination may use a larger collection vessel, if available.
- 6.4 *Athletes with visual impairment*
- 6.4.1 *Athletes* may be accompanied by an Athlete Representative at all times during the sample collection procedure, including in the toilet area. However, the representative shall not witness the passing of the sample. The objective is to ensure that the Witness is observing sample provision correctly.
- 6.4.2 The Athlete Representative or the DCO shall read the doping control documentation to the *Athlete*, if necessary.
- 6.4.3 Blind *Athletes* must be accompanied for the verification of procedure (signing of the Doping Control Form), and the Athlete Representative shall sign on behalf of or in addition to the *Athlete*.
- 6.5 *Athletes with an intellectual disability*
- 6.5.1 *Athletes* shall be accompanied by an Athlete Representative at all times during sample collection procedure, including in the toilet area. However, the representative shall not witness the passing of the sample. The objective is to ensure that the Witness is observing sample provision correctly.
- 6.5.2 The Athlete Representative or the DCO shall read and/or explain the Doping Control documentation to the *Athlete*, if necessary.
- 6.5.3 *Athletes* with a intellectual disability must be accompanied for the verification of procedure (signing of the Doping Control Form), and the Athlete Representative shall sign on behalf of or in addition to the *Athlete*.
- 6.6 *Athletes using condom drainage or indwelling catheter drainage*
- 6.6.1 *Athletes* shall remove, or supervise the removal of, the existing collection bag and drain the system so that a fresh sample can be obtained.
- 6.7 *Athletes who self-catheterize*
- 6.7.1 *Athletes* may use their own catheter to provide a sample (this catheter should be produced in tamper-evident wrapping), or use one provided at the *Doping Control Station*, if available.

Appendix 1: Chaperone Training Guidelines

A. Procedure for training notifying Chaperones

1. The notifying Chaperones shall meet the Lead DCO at the *Doping Control Station* prior to the start of the event to receive training, instruction, credentials and assignments, as well as to complete a confidentiality agreement.
2. The Lead DCO shall first ensure that the notifying Chaperones meet the relevant criteria as specified by the ADO and are fit for duty. If not, alternative Chaperones should be found.
3. The Lead DCO shall specifically ask the notifying Chaperones if they have any conflict of interest, such as involvement with any *Athlete* that might be tested. If so, alternative Chaperones should be found.
4. The Lead DCO shall ensure that all notifying Chaperones have a watch, and all staff should synchronize their watches.
5. The Lead DCO shall review or arrange for the review of the notification and escorting procedure with the notifying Chaperones. (5.5/5.6) The explanation should include the purpose of the Chaperone role, and what to do if problems are encountered. The DCO should make it clear that a Chaperone should ask for assistance from the Lead DCO if they are not sure how to proceed at any time.
6. The DCO shall demonstrate the notification procedure by means of role-play, should observe the Chaperone practice at least once, and point out mistakes as well as providing praise.
7. The DCO shall inform the Chaperones that any strange behavior by *Athletes*, such as ingestion of unknown substances, or evasion, should be discretely reported to the Lead DCO upon arrival at the *Doping Control Station*.
8. The DCO shall encourage questions from the Chaperones.
9. The Lead DCO shall arrange a location and time for the Chaperones to receive information specific to the *Athlete* they will be notifying.

NOTE: whenever possible, notifying Chaperones should be assigned to *Athletes* of the same gender.

10. Notifying Chaperones shall then sign the relevant agreement which should as a minimum require a commitment to confidentiality and outline a code of conduct. The form should also require the Notifying Chaperone to provide their contact details and date of birth.

11. The Chaperones shall, where possible, have an opportunity to assess the location and plan the approach and timing of notification, taking into account the specific circumstances of the session.
12. The Lead DCO shall provide guidelines as to the Chaperone's responsibilities after the *Athlete* has arrived at the *Doping Control Station* (i.e. whether they are free to leave, or have further responsibilities).

B Procedure for training witnessing Chaperones

Ideally, witnessing Chaperones will have prior experience, and will not be trained on-site.

1. The witnessing Chaperones shall meet the Lead DCO at the *Doping Control Station* prior to the start of the event to receive training, instruction, credentials and assignments, as well as to complete the confidentiality agreement. Training should be separate from that of the Notifying Chaperones.
2. The Lead DCO shall first ensure that the witnessing Chaperones meet the relevant criteria as specified by the ADO and are fit for duty. If not, alternative Chaperones should be found.
3. The Lead DCO shall specifically ask the Chaperones if they have any conflict of interest, such as involvement with any *Athlete* that might be tested. If not, alternative Chaperones should be found.
4. The Lead DCO shall review, or arrange the review of, the specific procedure for observation of sample provision (5.9).
5. Witnessing Chaperones shall also be briefed about any sensitivities, and any potential scenarios which might be encountered.
6. The DCO shall encourage questions from the Chaperones.
7. Witnessing Chaperones shall then sign the relevant agreement which should as a minimum require a commitment to confidentiality and outline a code of conduct. The form should also require the Witnessing Chaperone to provide their contact details and date of birth.
8. The Lead DCO shall provide guidelines as to the Chaperone's responsibilities after the *Athlete* has provided the Sample at the *Doping Control Station* (i.e. whether they are free to leave, or have further responsibilities).

WADA Technical Document – TD2003IDCR

| | | | |
|------------------|-------------------|-----------------|-----------------|
| Document Number: | TD2003IDCR | Version Number: | 1.2 |
| Written by: | WADA Project Team | Approved by: | |
| Date: | May 11, 2003 | Effective Date: | January 1, 2004 |

IDENTIFICATION CRITERIA FOR QUALITATIVE ASSAYS INCORPORATING CHROMATOGRAPHY AND MASS SPECTROMETRY

The appropriate analytical characteristics must be documented for a particular assay. The Laboratory must establish criteria for identification of a compound. Examples of acceptable criteria are:

Chromatographic separation

For capillary gas chromatography, the retention time (RT) of the analyte shall not differ by more than one (1) percent or ± 0.2 minutes (whichever is smaller) from that of the same substance in a spiked urine sample, Reference Collection sample, or Reference Material analyzed contemporaneously. In those cases where shifts in retention can be explained, for example by sample overload, the retention time criteria may be relaxed. For high performance liquid chromatography, the RT of the analyte shall not differ by more than two (2) percent or ± 0.4 minutes (whichever is smaller) from that of the same substance in a spiked urine sample, Reference Collection sample, or Reference Material analyzed in the same analytical batch.

Mass Spectrometric Detection

Full scan mode: A full or partial **scan** is the preferred approach to identification. A partial **scan** may begin at an m/z value greater than any abundant ion due to the derivatizing agent or chemical ionization reagent.

When a full or partial **scan** is acquired, all **diagnostic ions** with a **relative abundance** greater than 10% in the reference spectrum obtained from a positive control urine, a Reference Collection sample, or a Reference Material must be present in the spectrum of the unknown peak. In addition, the **relative abundance** of three **diagnostic ions** shall not differ by more than the amount shown in Table 1 from the relative intensities of the same ions from that of a spiked urine, a Reference Collection sample, or a Reference Material. The **relative abundance** of the **diagnostic ions** may be obtained from single or averaged spectra or integration of peak areas of extracted ion profiles.

Background subtraction, if applied, should be performed uniformly on all *Samples* analyzed contemporaneously and used to make decisions regarding the presence of a *Prohibited Substance* or *Method*, its *Metabolite*, or *Marker*.

The use of computer-based mass spectral library searching or matching is permitted. The laboratory must establish criteria for acceptance of compound identification based on spectral match quality. Since the match factor of a reverse search does not guarantee identification, all spectral library matches must be reviewed by a qualified scientist.

If three **diagnostic ions** with a **relative abundance** greater than 5% are not available, a second derivative shall be prepared, or a second ionization or fragmentation technique shall be used. The second derivative should yield different

WADA Technical Document – TD2003IDCR

| | | | |
|------------------|-------------------|-----------------|-----------------|
| Document Number: | TD2003IDCR | Version Number: | 1.2 |
| Written by: | WADA Project Team | Approved by: | |
| Date: | May 11, 2003 | Effective Date: | January 1, 2004 |

diagnostic ions. The second ionization technique must be based on a different physical principle, i.e., chemical ionization vs. electronic ionization and again should provide different diagnostic ions. It is not acceptable to utilize a technique that changes only the **relative abundance** of the same mass ions. In any case, a minimum of two **diagnostic ions** is mandatory in each mass spectrum.

Selected Ion Monitoring Mode: In some cases, it may be necessary to monitor selected ions in order to detect the substance at the Minimum Required Performance Limits. When selected ions are monitored, at least three **diagnostic ions** must be acquired. The **relative abundance** of a **diagnostic ion** shall preferably be determined from the peak area or height of integrated selected ion chromatograms. The **signal-to-noise ratio** of the least intense **diagnostic ion** must be greater than three to one (3:1). The relative intensities of any of the ions shall not differ by more than the amount in Table 1 from the relative intensities of the same ions acquired from a spiked urine, Reference Collection sample, or Reference Material. For a **diagnostic ion** with a **relative abundance** of less than 5% in the reference, the ion must be present in the unknown. The concentration of *Prohibited Substance*, or its *Metabolite*, or its *Marker* should be comparable in the *Sample* and the spiked urine, Reference Collection sample, or Reference Material.

Table 1
Maximum Tolerance Windows for Relative Ion Intensities
to Ensure Appropriate Uncertainty in Identification

| Relative Abundance (% of base peak) | EI-GC/MS | CI-GC/MS; GC/MS ⁿ ; LC/MS ; LC/MS ⁿ |
|--|------------------|---|
| > 50% | ±10% (absolute) | ± 15% (absolute) |
| 25% to 50% | ± 20% (relative) | ±25% (relative) |
| < 25% | ±5% (absolute) | ±10% (absolute) |

If the Laboratory protocol requires three ions to be within a tolerance window to identify a substance, it is not permissible to collect additional ions and select those ion ratios that are within tolerance and ignore others that would not result in meeting identification criteria without a valid explanation.

If three **diagnostic ions** are not available, a second derivative shall be prepared, or a second ionization or fragmentation technique shall be used. The second derivative should yield different **diagnostic ions**. The second ionization technique must be based on a different physical principle, i.e., chemical ionization vs. electronic ionization and again should provide different **diagnostic ions**. It is not acceptable to utilize a technique that changes only the **relative abundance** of the

WADA Technical Document – TD2003IDCR

| | | | |

| Date: | May 11, 2003 | Effective Date: | January 1, 2004 |

Definitions

Diagnostic ion(s): Molecular ion or fragment ions whose presence and abundance are characteristic of the substance and thereby may assist in its identification. A second ion belonging to the same isotopic cluster may also be used as diagnostic only when the peculiarity of the atomic composition of the fragment so justifies (e.g. presence of Cl, Br, or other elements with abundant isotopic ions).

High resolution mass spectrometry (HRMS): For the purposes of the *International Standards for Laboratories*, HRMS is defined as mass spectrometry at a resolving power (10 % valley definition) in excess of 3,000.

Low resolution mass spectrometry (LRMS): LRMS is defined as mass spectrometry at a resolving power (10 % valley definition) lower than 3,000.

Relative abundance (mass spectrometry): The abundance of a particular ion relative to the most abundant ion monitored expressed as a percentage.

Maximum difference in relative abundance: The maximum permitted difference between the relative abundance of a particular ion obtained from the *Sample* and that obtained from the positive control urine. This may be expressed in ABSOLUTE or RELATIVE terms.

Absolute difference: Calculated by subtracting the stated percentage from the relative abundance obtained for the studied ion from the positive control urine or Reference Material. For example, if the relative abundance of an ion in the chromatographic peak of interest in the positive control urine or Reference Material is measured as 20%, then the observed relative abundance for the same ion in the peak of interest in the unknown urine sample would be required to be in the range of 15-25% ($20\% \pm 5\%$) for the ion to contribute to an acceptable identification.

Relative difference: Calculated by multiplying the stated percentage by the relative abundance obtained for the studied ion from the positive control urine or Reference Material. For example, if the relative abundance of an ion in the chromatographic peak of interest in the positive control urine or Reference Material appears as 30 % and the stated maximum permitted difference is 20 % (relative), then the observed relative abundance for the same ion in the peak of interest in the unknown urine sample would be required to be in the range of 24-36% ($30\% \pm (30 \times 20\%)$) for the ion to contribute to an acceptable identification.

Scan: Acquisition of ions of a continuous range of m/z values.

Selected ion monitoring (SIM): Acquisition of ions of one or more pre-determined discrete m/z values for specified dwell times.

WADA Technical Document – TD2003IDCR

|------------------|-------------------|-----------------|-----------------|
| Document Number: | TD2003IDCR | Version Number: | 1.2 |
| Written by: | WADA Project Team | Approved by: | |
| Date: | May 11, 2003 | Effective Date: | January 1, 2004 |

Signal-to-Noise Ratio: Magnitude of the instrument response to the analyte (signal) relative to the magnitude of the background (noise).

Tandem mass spectrometry (MS/MS or MSⁿ): A technique in which a precursor ion is isolated in a mass analyzer, fragmented by collision with a collision gas, and the product ions collected in a second mass analyzer. This process can be applied multiple times, each application being reflected in the "n" exponent. The technique may be accomplished either in space (e.g. triple quadrupole MS) or in time (e.g. ion trap MS)

Data File : K:\CHEM\AAS\CONFIRM\MSDA13\9CS03LR.D

ISTD Ethylmorphine

Total Ion Chromatogram

Testosterone

Handwritten signature/initials

GC/C/IRMS - Results

26.02.03

Federation: [REDACTED]

Event: [REDACTED]

Code-Nr.: 188702

Lab-Nr.: 1013/03 A

Sample receipt: 11.02.03

Results: The ratio testosterone/epitestosterone is higher than 6
(25.3 ± 0.31, n=3); the GC/C/IRMS results indicate an application
of testosterone or testosterone prohormones

For the sample with the code number 188702 the following $\delta^{13}\text{C}$ [‰] - values were obtained:

testosterone metabolites:

etiocholanolone - 30.5 ± 0.2 (n=5)

androsterone - 29.5 ± 0.3 (n=5)

internal reference compounds:

11 β -hydroxy-androsterone - 20.46; - 20.17

pregnanediol - 21.1 ± 0.1 (n=3)

Conclusions

The $\delta^{13}\text{C}$ [‰]-values of the testosterone metabolites indicate the application of testosterone
or testosterone prohormones.

Code: 188702

Decision criterias for GC/C/IRMS results

Based on our reference values the following criterias indicate an application of testosterone or testosterone prohormones:

Difference of the $\delta^{13}\text{C}$ [‰]- values between androsterone and pregnanediol > 2.6 or
difference between the $\delta^{13}\text{C}$ [‰]- values of etiocholanolone and pregnanediol > 3.3

SUBSTANCES & METHODS PROHIBITED AT ALL TIMES

IN- AND OUT-OF-COMPETITION

PROHIBITED SUBSTANCES

S1. ANABOLIC AGENTS

Anabolic agents are prohibited.

1. Anabolic Androgenic Steroids (AAS)

a. Exogenous* AAS, including:

| | |
|--|-----------------------|
| 18 α -homo-17 β -hydroxyestr- 4-en-3-one | metenolone |
| bolasterone | methandienone |
| boldenone | methandriol |
| boldione | methyldienolone |
| calusterone | methyltrienolone |
| clostebol | methyltestosterone |
| danazol | mibolerone |
| dehydrochloromethyl- testosterone | nandrolone |
| delta1-androstene-3,17-dione | 19-norandrostenediol |
| delta1-androstenediol | 19-norandrostenedione |
| delta1-dihydro-testosterone | norbolethone |
| drostanolone | norclostebol |
| ethylestrenol | norethandrolone |
| fluoxymesterone | oxabolone |
| formebolone | oxandrolone |
| furazabol | oxymesterone |
| gestrinone | oxymetholone |
| 4-hydroxytestosterone | quinbolone |
| 4-hydroxy-19-nortestosterone | stanozolol |
| mestanolone | stenbolone |
| mesterolone | tetrahydrogestrinone |
| | trenbolone |

and other substances with a similar chemical structure or similar biological effect(s).

*"exogenous" refers to a substance which is not capable of being produced by the body naturally.

THE 2005 PROHIBITED LIST

05

b. Endogenous** AAS:

androstenediol (androst-5-ene-3 β ,17 β -diol)
androstenedione (androst-4-ene-3,17-dione)
dehydroepiandrosterone (DHEA)
dihydrotestosterone
testosterone

and the following metabolites and isomers:

5 α -androstane-3 α ,17 α -diol
5 α -androstane-3 α ,17 β -diol
5 α -androstane-3 β ,17 α -diol
5 α -androstane-3 β ,17 β -diol
androst-4-ene-3 α ,17 α -diol
androst-4-ene-3 α ,17 β -diol
androst-4-ene-3 β ,17 α -diol
androst-5-ene-3 α ,17 α -diol
androst-5-ene-3 α ,17 β -diol
androst-5-ene-3 β ,17 α -diol
4-androstenediol (androst-4-ene-3 β ,17 β -diol)
5-androstenedione (androst-5-ene-3,17-dione)
epi-dihydrotestosterone
3 α -hydroxy-5 α -androstan-17-one
3 β -hydroxy-5 α -androstan-17-one
19-norandrosterone
19-noretiocholanolone

Where a *Prohibited Substance* (as listed above) is capable of being produced by the body naturally, a *Sample* will be deemed to contain such *Prohibited Substance* where the concentration of the *Prohibited Substance* or its metabolites or markers and/or any other relevant ratio(s) in the *Athlete's Sample* so deviates from the range of values normally found in humans that it is unlikely to be consistent with normal endogenous production. A *Sample* shall not be deemed to contain a *Prohibited Substance* in any such case where the *Athlete* proves by evidence that the concentration

** "endogenous" refers to a substance which is capable of being produced by the body naturally.

of the *Prohibited Substance* or its metabolites or markers and/or the relevant ratio(s) in the *Athlete's Sample* is attributable to a physiological or pathological condition. In all cases, and at any concentration, the laboratory will report an *Adverse Analytical Finding* if, based on any reliable analytical method, it can show that the *Prohibited Substance* is of exogenous origin.

If the laboratory result is not conclusive and no concentration as referred to in the above paragraph is found, the relevant *Anti-Doping Organization* shall conduct a further investigation if there are serious indications, such as a comparison to reference steroid profiles, for a possible *Use of a Prohibited Substance*.

If the laboratory has reported the presence of a T/E ratio greater than four (4) to one (1) in the urine, further investigation is obligatory in order to determine whether the ratio is due to a physiological or pathological condition, except if the laboratory reports an *Adverse Analytical Finding* based on any reliable analytical method, showing that the *Prohibited Substance* is of exogenous origin.

In case of an investigation, it will include a review of any previous and/or subsequent tests. If previous tests are not available, the *Athlete* shall be tested unannounced at least three times within a three month period.

Should an *Athlete* fail to cooperate in the investigations, the *Athlete's Sample* shall be deemed to contain a *Prohibited Substance*.

2. Other Anabolic Agents, including but not limited to:

clenbuterol
zeranol
zilepaterol

S2. HORMONES AND RELATED SUBSTANCES

The following substances, including other substances with a similar chemical structure or similar biological effect(s), and their releasing factors, are prohibited.

1. Erythropoietin (EPO)
2. Growth Hormone (hGH), Insulin-like Growth Factor (IGF-1), Mechano Growth Factors (MGFs)
3. Gonadotrophins (LH, hCG)
4. Insulin
5. Corticotrophins

Unless the *Athlete* can demonstrate that the concentration was due to a physiological or pathological condition, a *Sample* will be deemed to contain a *Prohibited Substance* (as listed above) where the concentration of the *Prohibited Substance* or its metabolites and/or relevant ratios or markers in the *Athlete's Sample* so exceeds the range of values normally found in humans so that it is unlikely to be consistent with normal endogenous production.

The presence of other substances with a similar chemical structure or similar biological effect(s), diagnostic marker(s) or releasing factors of a hormone listed above or of any other finding which indicate(s) that the substance detected is of exogenous origin, will be reported as an *Adverse Analytical Finding*.

S3. BETA-2 AGONISTS

All beta-2 agonists including their D- and L-isomers are prohibited. Their use requires a Therapeutic Use Exemption.

As an exception, formoterol, salbutamol, salmeterol and terbutaline, when administered by inhalation to prevent and/or treat asthma and exercise-induced asthma/broncho-constriction require an abbreviated Therapeutic Use Exemption.

Despite the granting of a Therapeutic Use Exemption, when the Laboratory has reported a concentration of salbutamol (free plus glucuronide) greater than 1000 ng/mL, this will be considered as an *Adverse Analytical Finding* unless the athlete proves that the abnormal result was the consequence of the therapeutic use of inhaled salbutamol.

S4. AGENTS WITH ANTI-ESTROGENIC ACTIVITY

The following classes of anti-estrogenic substances are prohibited:

1. Aromatase inhibitors including, but not limited to:

| | |
|-------------------|--------------|
| anastrozole | formestane |
| aminoglutethimide | letrozole |
| exemestane | testolactone |

2. Selective Estrogen Receptor Modulators (SERMs) including, but not limited to:

raloxifene
tamoxifen
toremifene

3. Other anti-estrogenic substances including, but not limited to:

clomiphene
cyclofenil
fulvestrant

S5. DIURETICS AND OTHER MASKING AGENTS

Diuretics and other masking agents are prohibited.
Masking agents include but are not limited to:

diuretics*
epitestosterone
probenecid
alpha-reductase inhibitors
(e.g. finasteride, dutasteride)
plasma expanders
(e.g. albumin, dextran, hydroxyethyl starch)

Diuretics include:

| | |
|----------------|--|
| acetazolamide | indapamide |
| amiloride | metolazone |
| bumetanide | spironolactone |
| canrenone | thiazides (e.g. bendroflumethiazide, chlorothiazide, hydrochlorothiazide) |
| chlortalidone | triamterene |
| etacrynic acid | |
| furosemide | |

and other substances with a similar chemical structure or similar biological effect(s).

* A Therapeutic Use Exemption is not valid if an Athlete's urine contains a diuretic in association with threshold or sub-threshold levels of a Prohibited Substance(s).

PROHIBITED METHODS

M1. ENHANCEMENT OF OXYGEN TRANSFER

The following are prohibited:

- a. Blood doping, including the use of autologous, homologous or heterologous blood or red blood cell products of any origin, other than for medical treatment.
- b. Artificially enhancing the uptake, transport or delivery of oxygen, including but not limited to perfluorochemicals, efaproxiral (RSR13) and modified haemoglobin products (e.g. haemoglobin-based blood substitutes, microencapsulated haemoglobin products).

M2. CHEMICAL AND PHYSICAL MANIPULATION

The following is prohibited:

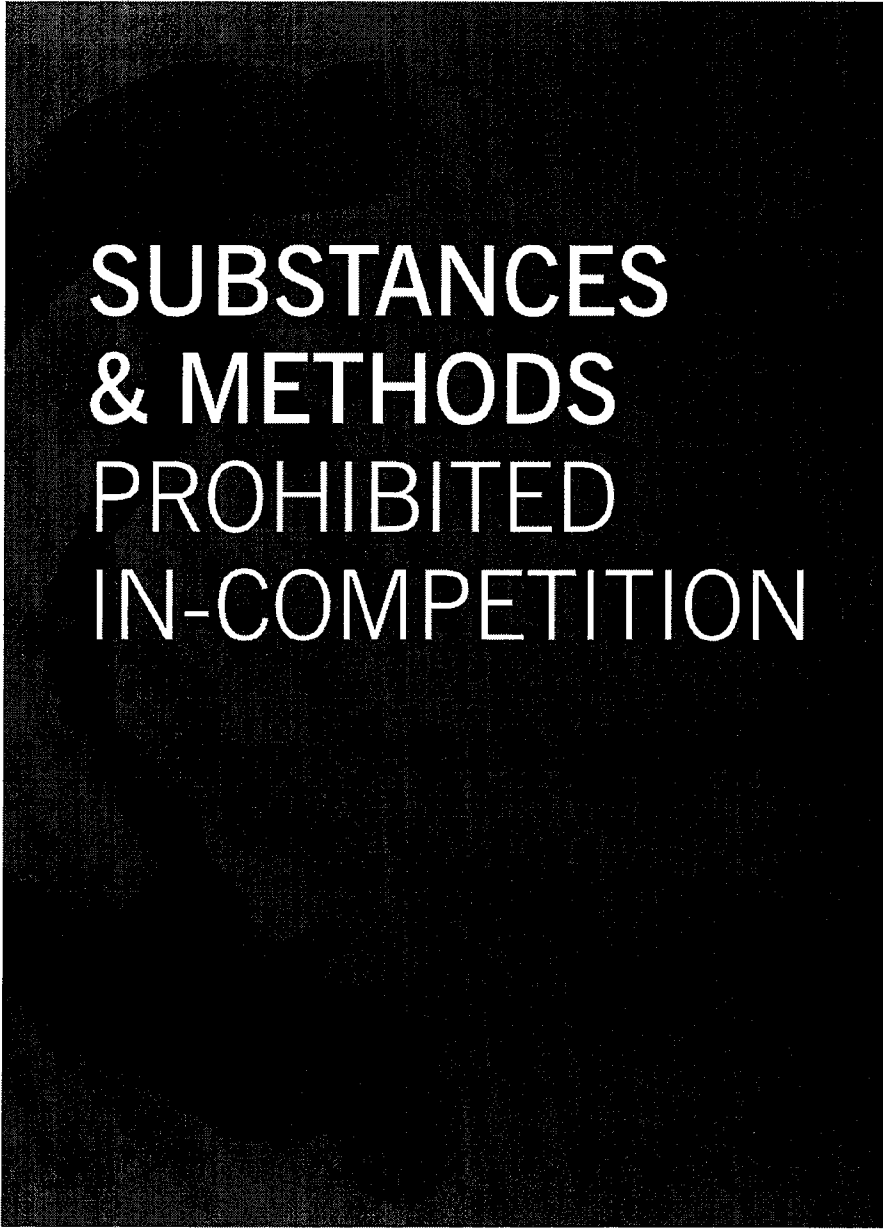

Tampering, or attempting to tamper, in order to alter the integrity and validity of *Samples* collected in *Doping Controls*.

These include but are not limited to intravenous infusions*, catheterization, and urine substitution.

M3. GENE DOPING

The non-therapeutic use of cells, genes, genetic elements, or of the modulation of gene expression, having the capacity to enhance athletic performance, is prohibited.

* Except as a legitimate acute medical treatment, intravenous infusions are prohibited.

A dark, textured rectangular area, possibly a book cover or a graphic element, with white text centered on it. The text is in a bold, sans-serif font and is arranged in four lines.

SUBSTANCES & METHODS PROHIBITED IN-COMPETITION

In addition to the previously listed categories S1, S2, S3, S4, S5 and M1, M2, M3, the following are prohibited *in-competition*:

S6. STIMULANTS

The following stimulants are prohibited, including both their optical (D- and L-) isomers where relevant:

| | |
|---------------------|-------------------------------|
| adrafinil | furfenorex |
| amfepramone | mefenorex |
| amiphenazole | mephentermine |
| amphetamine | mesocarb |
| amphetaminil | methamphetamine |
| benzphetamine | methylamphetamine |
| bromantan | methylenedioxymphetamine |
| carphedon | methylenedioxymethamphetamine |
| cathine* | methylephedrine** |
| clobenzorex | methylphenidate |
| cocaine | modafinil |
| dimethylamphetamine | nikethamide |
| ephedrine** | norfenfluramine |
| etilamphetamine | parahydroxyamphetamine |
| etilefrine | pemoline |
| famprofazone | phendimetrazine |
| fencamfamin | phenmetrazine |
| fencamine | phentermine |
| fenetylline | prolintane |
| fenfluramine | selegiline |
| fenproporex | strychnine |

and other substances with a similar chemical structure or similar biological effect(s)***.

NOTE: Adrenaline associated with local anaesthetic agents or by local administration (e.g. nasal, ophthalmologic) is not prohibited.

* Cathine is prohibited when its concentration in urine is greater than 5 micrograms per milliliter.

** Each of ephedrine and methylephedrine is prohibited when its concentration in urine is greater than 10 micrograms per milliliter.

*** The substances included in the 2005 Monitoring Program (bupropion, caffeine, phenylephrine, phenylpropanolamine, pipradrol, pseudoephedrine, synephrine) are not considered as Prohibited Substances.

S7. NARCOTICS

The following narcotics are prohibited:

| | |
|------------------------------|-------------|
| buprenorphine | morphine |
| dextromoramide | oxycodone |
| diamorphine (heroin) | oxymorphone |
| fentanyl and its derivatives | pentazocine |
| hydromorphone | pethidine |
| methadone | |

S8. CANNABINOIDS

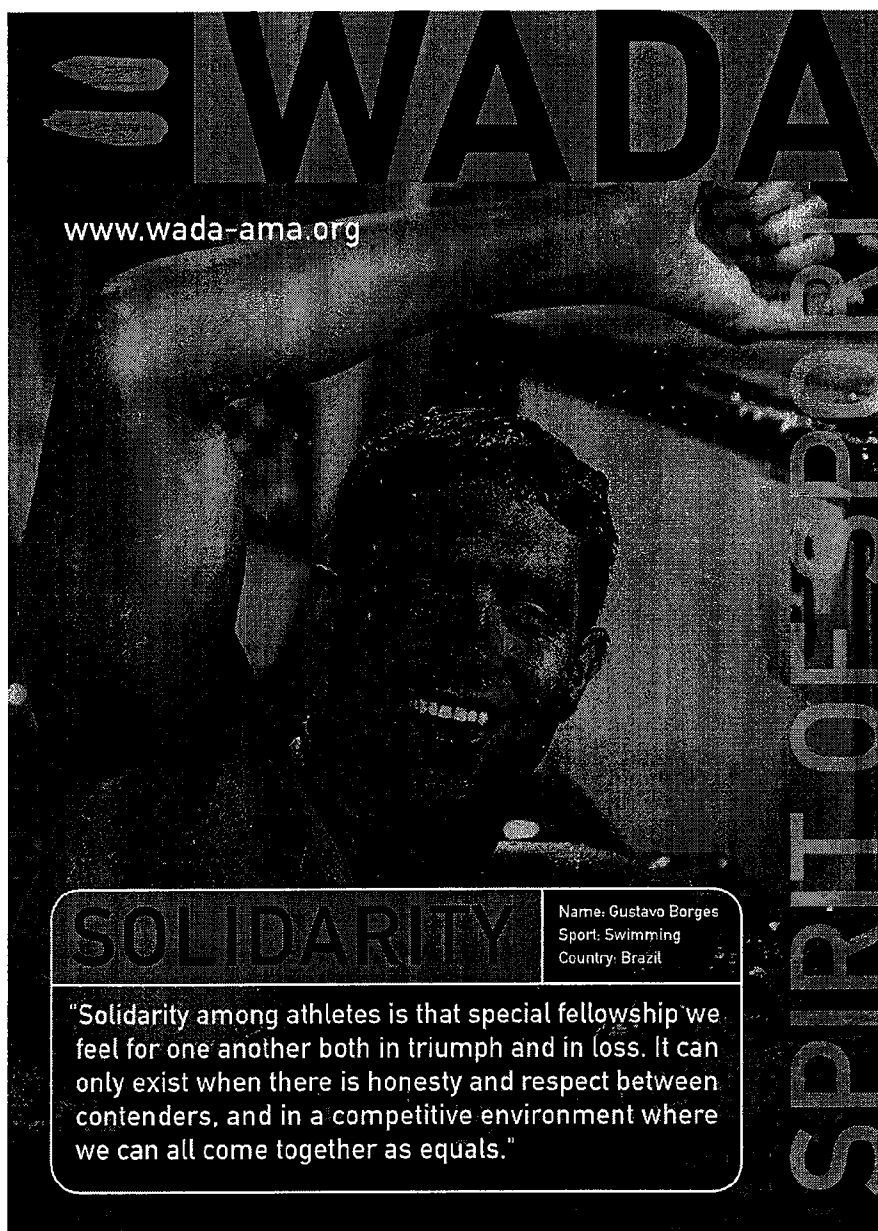

Cannabinoids (e.g. hashish, marijuana) are prohibited.

S9. GLUCOCORTICOSTEROIDS

All glucocorticosteroids are prohibited when administered orally, rectally, intravenously or intramuscularly. Their use requires a Therapeutic Use Exemption approval.

All other routes of administration require an abbreviated Therapeutic Use Exemption.

Dermatological preparations are not prohibited.

SOLIDARITY

Name: Gustavo Borges
Sport: Swimming
Country: Brazil

"Solidarity among athletes is that special fellowship we feel for one another both in triumph and in loss. It can only exist when there is honesty and respect between contenders, and in a competitive environment where we can all come together as equals."

SPIRIT OF SPORT

SUBSTANCES PROHIBITED IN PARTICULAR SPORTS

PROHIBITED SUBSTANCES

P1. ALCOHOL

Alcohol (ethanol) is prohibited *in-competition* only, in the following sports. Detection will be conducted by analysis of breath and/or blood. The doping violation threshold for each Federation is reported in parenthesis.

| | |
|--|------------|
| Aeronautic (FAI) | (0.20 g/L) |
| Archery (FITA) | (0.10 g/L) |
| Automobile (FIA) | (0.10 g/L) |
| Billiards (WCBS) | (0.20 g/L) |
| Boules (CMSB) | (0.10 g/L) |
| Karate (WKF) | (0.10 g/L) |
| Modern Pentathlon (UIPM) for disciplines involving shooting | (0.10 g/L) |
| Motorcycling (FIM) | (0.00 g/L) |
| Skiing (FIS) | (0.10 g/L) |

P2. BETA-BLOCKERS

Unless otherwise specified, beta-blockers are prohibited *in-competition* only, in the following sports:

Aeronautic (FAI)
 Archery (FITA) (also prohibited *out-of-competition*)
 Automobile (FIA)
 Billiards (WCBS)
 Bobsleigh (FIBT)
 Boules (CMSB)
 Bridge (FMB)
 Chess (FIDE)
 Curling (WCF)
 Gymnastics (FIG)
 Motorcycling (FIM)
 Modern Pentathlon (UIPM) for disciplines involving shooting
 Nine-pin bowling (FIQ)
 Sailing (ISAF) for match race helms only
 Shooting (ISSF) (also prohibited *out-of-competition*)
 Skiing (FIS) in ski jumping & free style snow board
 Swimming (FINA) in diving & synchronised swimming
 Wrestling (FILA)

Beta-blockers include, but are not limited to, the following:

| | | |
|------------|--------------|-------------|
| acebutolol | carvedilol | nadolol |
| alprenolol | celiprolol | oxprenolol |
| atenolol | esmolol | pindolol |
| betaxolol | labetalol | propranolol |
| bisoprolol | levobunolol | sotalol |
| bunolol | metipranolol | timolol |
| carteolol | metoprolol | |

SPECIFIED SUBSTANCES

"Specified Substances"* are listed below.

ephedrine
L-methylamphetamine
methylephedrine
cannabinoids
all inhaled beta-2 agonists, except clenbuterol
probenecid
all glucocorticosteroids
all beta blockers
alcohol

* "The Prohibited List may identify specified substances which are particularly susceptible to unintentional anti-doping rule violations because of their general availability in medicinal products or which are less likely to be successfully abused as doping agents. "A doping violation involving such substances may result in a reduced sanction provided that the Athlete can establish that the use of such a specified substance was not intended to enhance sport performance..."

ionisation modes, i.e. ESI and APCI, can be employed for the detection of steroid glucuronide conjugates, and main reasons for inconclusive results are based on chromatographic issues.

Acknowledgements

The scientific support of Dr. Michel Niesen is gratefully acknowledged by the project consortium as well as the cooperation with RIKIL, Institute of Food Safety and the doping control laboratories of Kneissle, London and Oslo.

Urine stability, steroid profile and T/E ratio: towards an index of sample degradation

Laboratorio Antidoping, Federazione Medico Sportiva Italiana, Roma, Italy

Introduction

The last revision of the WADA list reduced the threshold value for an elevated testosterone/epitestosterone (T/E) concentration ratio from 6 to 4. The WADA also released a technical document [1], which calls to assess sample degradation. A preliminary retrospective evaluation of the samples received in the summer months of the last three years confirmed the empirical evidence that the degradation of the sample is often associated to an increase of T/E value, and that this pattern, especially now that the threshold of the T/E ratio has been reduced, can generate an additional workload for the laboratories.

We have tried to identify one or more suitable markers of sample degradation that, based on the data obtained by other antidoping laboratories [2-6], could be evaluated directly, possibly at the screening stage, reducing the need for additional confirmation and/or quantification procedures of endogenous steroid hormones. Different potential markers of urine degradation (pH, metabolic by-products, deconjugated steroids and the variation of the concentration of testosterone, epitestosterone, DHT and DHEA in both total and free fraction) were considered; particularly, the effect of the storage temperature and of the urinary pH on the variation of the concentration of representative endogenous steroids, in both free and conjugated fraction, was considered, with the aim of verifying whether it would be possible to understand, directly from the screening procedures for the steroid hormones in the total and in the free fraction, whether a sample is to be considered degraded, thus avoiding unnecessary, time-consuming confirmation analysis. The significance of the proposed parameters was evaluated reconsidering all the data on the steroid fraction obtained on more than 2000 samples received by our laboratory in the period May-September 2004.

EXPERIMENTAL SECTION

In all experiments the urines underwent the screening procedures for both total and free anabolic steroids and analysed by GC/MS. The relative concentrations of the following steroids (glucuronate+free fraction) were measured: testosterone (Testo), epitestosterone (epiT), dehydroepiandrosterone (DHEA), dihydrotestosterone (DHT), 5 α -androstanedione and 5 β -androstanedione.

Constant temperature study

Experiments have been carried out on 10 different pools of urines, collected for two days. One aliquot of 3 mL of each pool was immediately taken for endogenous steroids analysis (free and conjugated fraction). Each pool was divided in four groups, stored at different temperatures (-20 °C, 4 °C, 25 °C and 37 °C) for 20 days.

Fixed pH study

Experiments have been carried out on 6 different pools of urines, collected for two days. One aliquot of 3 mL of each pool was immediately taken for steroids analysis (free and conjugated fraction), then each pool of urine was divided in three groups (two pool each groups) and stored at 25 °C and 37 °C and at pH 5, 7 and 9. The pH values were checked daily, and, if necessary, adjusted. The characterization of the samples was carried out following the degradation of a non-buffered group of samples, analyzed concurrently.

Reference standards

The standards were obtained by NARL-Australia (testosterone, epitestosterone), and by Sigma Aldrich (dehydroepiandrosterone, dihydrotestosterone, 5 α -androstanedione and 5 β -androstanedione).

Analytical procedure

To 3 mL of urine, 50 μ L of internal standard (17 α -methyltestosterone), 1 mL of 0.2M phosphate buffer pH=7.4, and 30 μ L of beta-glucuronidase from *E. coli* were added and hydrolysis was performed for 1 h at 50 °C. The buffered solution was then alkalized with 1 mL of carbonate buffer and the steroids were extracted with 10 mL of tert-butylmethyl ether on a mechanical shaker for 5 minutes. After centrifugation, the ethereal layer was transferred and evaporated to dryness under vacuum; the residue was derivatized by 50 μ L of N-methyl-N-trimethylsilyl-trifluoroacetamide (MSTFA):NH₄LiDiethoxyethylol (1000:2:4 v/w/w) and 1 μ L of the derivatized extract was injected directly into the injection port. The sample preparation for the screening analysis of the free fraction consisted only in a liquid-liquid extraction at pH 9 and derivatization with the same reagent used for the total fraction.

Quantitation of excreted steroids (free and conjugated fraction) was performed by GC/MS on an Agilent 5890V 5973A, in electron impact (70 eV), using a 17 m fused silica capillary column cross-linked methyl silicone (HP1-1D 0.20 mm, film thickness 0.11 μ m). The carrier gas was helium (flow rate: 1 mL/min, split ratio 1:10), and the temperature program was as follows: 180 °C (hold 4.5 min), 3 °C/min to 230 °C, 20 °C/min to 290 °C, 30 °C/min to 320 °C; transfer line temperature: 280 °C. Acquisition was carried out in selected ion monitoring (SIM) of the following fragments: m/z 432 for testosterone, epitestosterone and DHEA; m/z 275 for 5 α -androstanedione and m/z 417 for 5 β -androstanedione. All values of urine concentration were calculated by the peak areas of the detected signals relative to the internal standard methyltestosterone (m/z 301). For calibration of the GC/MS instrument, the following reference mixtures were used (table 1 and table 2). All experimental data are reported in the figures 1-11.

Table1: Methanolic solutions

| Compound | Internal code | CalG1 50uL Conc. ng/mL (3 mL urine) | CalG2 50uL Conc. ng/mL (3 mL urine) |
|----------------------------|---------------|---|---|
| Testosterone | Test2-001 | 10 | 40 |
| Epitestosterone | Epi-002 | 10 | 40 |
| Androsterone | H047-002 | 500 | 1000 |
| Epiandrosterone | H080-001 | 500 | 1000 |

| Androstenedione | ASTB-001 | 10 | 20 |

RESULTS AND DISCUSSION

Influence of the temperature

From the data reported in Figures 1-3 it can be concluded that the most relevant parameters involved - and detectable - in the urine degradation process are the followings:

- formation (first in the conjugated fraction and then in the free fraction) of 5 α -androstanedione and 5 β -androstanedione: the urinary concentrations of these substances increase quickly during storage at 37 °C, more slowly at 25 °C. No difference (as far as the steroid profile is concerned) was detected, over a 20-day period, between 4 °C and - 20 °C;
- increased concentration of testosterone, epitestosterone, DHEA and DHT in the free fraction, recorded when the urine was stored at 37 °C;
- rapid increase and then decrease of DHT and DHEA in the conjugated fraction;
- increase of the pH value, recorded when the urine was stored either at 37 °C or at 25 °C.

Influence of pH

Figures 4-7 show that the effect of pH can be summarized as follows:

- the degradation is very rapid at 37 °C, slower but still pronounced at room temperature, while no difference (as far as the steroid profile is concerned) was detected between 4 °C and - 20 °C on a 30-day period;
- the pH value appears to be critical for the degradation process, i.e. at 37 °C: the process is very slow at pH 5.0. At pH 7.0 the process is very fast;
- the degradation is still quick at pH 9.0, but it goes on for a short time.

Parameters validation

In this phase we have studied ten pools of urine, with the aim of fixing a tentative cut-off value for the two most reliable markers of urine degradation, i.e. 5 α -androstanedione and 5 β -androstanedione. Data from Figures 8-11 show that when the percentage of epitestosterone and testosterone in the free fraction is higher than the 5% of the conjugated fraction, the value of 5 α -androstanedione and 5 β -androstanedione in the total fraction is around 7 and 20 ng/mL respectively. To validate this hypothesis we have reconsidered all the "A" samples (total: 2965) analyzed in our laboratory during the summer period (from May to September 2004).

The results of this retrospective study were the followings:

- 247 of these samples were found to match our degradation criteria;
- all those samples (27) with a T/E > 6, and subsequently found to be degraded, matched our degradation criteria;

reconsidering the new limit (T/E > 4), 138 had a T/E ratio (from the screening) imposing a confirmation analysis, and 43 (31%) could be considered degraded on the basis of the limits proposed for the screening analysis (TMS-derivatives, total fraction), without running any confirmation.

Figure 1. Variation as a function of time of the urinary concentration of 5 α -androstanedione (□), 5 β -androstanedione (■) and of the urinary pH (○), at 37 °C, both in the free (A) and in the conjugated (B) fraction.

Figure 2. Variation as a function of time of the urinary concentration of DHT (□), DHEA (■) and of the urinary pH (○), at 37 °C, both in the free (A) and in the conjugated (B) fraction.

Figure 3. Variation as a function of time of the urinary concentration of: Testosterone (□), Epitestosterone (■) and of the urinary pH (○), at 37 °C, both in the free (A) and in the conjugated (B) fraction.

Figure 4. Variation as a function of time of the urinary concentration of 5α-androstenedione (free fraction) at 37 °C, at pH 5 (black), 7 (dashed), 9 (grey) and in non-buffered pool (x).

CONCLUSIONS

- The lowering of the T/E ratio value from 5 to 4 increases a useful evaluation of biological markers of doping degradation (corresponding, according to ref. [1] to a testosterone and epitestosterone concentrations ratio free/conjugated = 5%), the full quantitative confirmation in the free and total fraction of the testosterone and epitestosterone concentration may exceed the overall capacity of the laboratory (especially in the summer months).
- If the screening "IVA" (TMS-derivatives, free fraction) is performed, the simple presence of 5α-androstenedione and 5β-androstenedione is a reliable index of sample degradation: a window in the screening macro is easily added and monitored (presence/absence).
- If only the screening "IVA" (TMS-derivatives, total fraction) is performed, the concentration of 5α-androstenedione and 5β-androstenedione in the total fraction above a confidence threshold value (respectively 7 ng/mL and 40 ng/mL, respectively) is a reliable index of sample degradation.
- Alternatively, the concentration of 5α-androstenedione and 5β-androstenedione can be estimated by the height ratio 5α/ISTD and/or 5β/ISTD (in our case deuterated epitestosterone). The instrumental stability and repeatability of these parameters suggest that the laboratory internal threshold can represent a valid index for the preliminary assessment of sample degradation.

The effect of the oral administration of propyphenazone on the urinary concentration of testosterone and 19-nortestosterone metabolites

Laboratorio Antidoping, Federazione Medico-Sportiva Italiana, Roma, Italy

INTRODUCTION

Propyphenazone belongs structurally to the group of pyrazolone derivatives and therapeutically to non-steroidal anti-inflammatory drugs (NSAID). It has also analgesic effects. It is generically used for the treatment of fever, pain during flu or cold and after vaccination [1-2]. The drug is not prescribed often nowadays because of the many significant side effects; the normal dose is 150-300 mg 1 to 3 times per day. Some athletes use pharmaceutical formulations containing propyphenazone during multi-days events to suppress pain.

This study originates from the observation of some unknown peaks detected in a considerable number of samples by the screening procedure for the anabolic steroids. The spectrum of these peaks corresponded to the propyphenazone metabolites (Figure 1). The same samples showed an unusually altered steroid profile (Table 1).

Table 1 Steroid profile of some representative real samples, found to contain propyphenazone metabolites

The Cologne protocol to follow up high testosterone/epitestosterone ratios

Institut für Biochemie, Deutsche Sporthochschule Köln, Germany

This lecture was held at the 11th and 12th Cologne Workshop on Dope Analysis 1993 and 1994.

Introduction

The most important parameter for the detection of doping with exogenous testosterone is an elevated ratio testosterone/epitestosterone (1, 2). Before a dope control sample is declared positive for testosterone, it has to be proven, according to the rules of the IOC (3), that the elevated ratio testosterone/epitestosterone is not natural. Therefore we have developed in cooperation with the Antidoping Commission of the International Cycling Federation (UCI) a complex protocol to follow up high testosterone/epitestosterone values. The main intention of this protocol is the prevention of false positive results.

The knowledge of the „normal“ steroidprofile as basis for the detection of doping with testosterone

The basis for the detection of doping with testosterone and other endogenous steroids is the knowledge of the „normal“ steroid profile, i.e. population based reference ranges of endogenous steroids. Therefore we have analysed within our screening procedure for anabolic steroids steroidprofiles of dope control urines for several years. All samples were analysed and quantified with the same method, which was described in detail several times (4, 5). In table 1 are presented the endogenous steroids, which are monitored for steroidprofiling in the Cologne laboratory.

Tab. 1: Retention times, retention indices and ion traces of the endogenous steroids which are monitored for steroidprofiling in the Cologne laboratory. Also added are the internal standards (all steroids as per-trimethylsilyl derivatives).

The descriptive statistics and the calculated population based reference ranges of the steroidprofile parameters are presented in table 2-5. All values and details of the statistical calculation (reference population, reference sample group etc.) are published in the thesis of S. RAUTH (6). The calculation of the population based reference ranges were performed according to a concept and to recommendations of the International Federation of Clinical Chemistry (IFCC). All concentrations are corrected to a urine density of 1.020 g/cm³.

Parameters for the detection of doping with testosterone

The application of exogenous testosterone leads to characteristic changes of the normal steroidprofile (1). The most obvious change is the **increase of the ratio TEST/EPIT**. A value of this parameter above the upper limit of the reference range, i.e. higher than 6, indicates a suspicion for testosterone doping. Beside the TEST/EPIT ratio, two other parameters are important for the detection of testosterone doping. These parameters are a **decreased ratio of AND/TEST** and an **increased concentration of TEST (cTEST)**.

If all three parameters are outside of the limits of the reference values (see table 6) and other influences, e.g. bacterial activities, can be excluded, there is a high probability, that the unnormal steroidprofile is caused by a testosterone application. But because the T/E ratio is the most sensitive parameter for the detection of doping with testosterone, a suspicion is already given, if the T/E ratio is higher than the upper reference limit.

Tab. 6: Parameters of the steroidprofile, which make a urine suspicious for an application of exogenous TEST.

| Parameter | Men | Women |
|------------------|-------|-------|
| TEST/EPIT | > 6 | > 6 |
| AND/TEST | < 20 | < 40 |
| c TEST [ng/ml] * | > 130 | > 60 |

* concentration corrected to a urine density of 1.020

To study, if the high T/E ratio is natural, caused by a testosterone application or caused by other influences, e.g bacterial, pathological or analytical influences, we start with the following protocol.

Screening results -Search for other factors which may increase the ratio TEST/EPIT

If there was found a ratio TEST/EPIT > 6 we look first in our screening results for other factors, which may lead, beside the TEST application, to increased TEST/EPIT ratios or change the other testosterone related parameters AND/TEST and cTEST. In our screening method we have included some controls to recognize these factors:

Mistakes in the sample preparation and changes of the GC/MS conditions may change the TEST/EPIT ratio and the other testosterone related parameters. This is controled by the use of the internal standards d3-TEST, d3-EPIT and d4-ETIO. The d3-TEST and d3-EPIT are

added to each sample in a ratio of 6:1 (90 ng/ml / 15 ng/ml) so that the ratios TEST/EPIT can be corrected (7).

Bacterial activities in the urine can be recognized by the presence of 5 α - and 5 β -androstandion (4), which are monitored in our screening procedure. Also high amounts of DHT are found. The AND/TEST ratios are often low. These changes of the steroidprofile are mostly connected with high pH values. Further studies of such samples have shown, that in all of these samples high amounts of the steroid glucuronides are hydrolysed, and that the urine contains different enzyme activities as 3-hydroxy-steroid-dehydrogenase activity or steroid- Δ -isomerase etc. which can transform unconjugated androsterone to 5 α -androstandion or unconjugated 5-androstendiol to testosterone (5). In these cases, the steroidprofile parameters are worthless and we stop the follow up protocol. We inform the federation about the presence of bacterias, which are mostly caused by insuitable transport or storage conditions and recommend to repeat the dope controls and to improve the transport and storage conditions.

Bacterial activities in the phosphate buffer used for the hydrolysis can not be recognized from our screening chromatograms. We control such side activities in the hydrolysis step by spiking a buffer solution with 5 μ g of 5-androstene-3 β ,17 β -diol and DHEA (8). If TEST or 5-androstendion is found after incubation of 1 hour at 50° C, the sample preparation has to be repeated.

We prevent such side activities by heating the buffer for several minutes before use (8).

Incomplete hydrolysis leads to a low and therefore suspicious ratio AND/TEST because AND-glucuronide is hydrolysed slower than TEST-glucuronide (5). We control the hydrolysis with the internal standard [2,2,3,4,4-²H₅]-androsterone-D-17-glucuronide, which is added in an amount of 500 ng/ml to each sample. In case of an incomplete hydrolysis, we repeat the sample preparation.

Incomplete derivatisation may lead to wrong steroidprofile values, e.g. to low AND/TEST values. The derivatisation is controlled by the monitoring of the ion 272 (molecular ion -90) for AND and ETIO, mono-TMS. If these two substances are detected, the derivatisation is

incomplete and we add to the derivatised sample (ca. 80 µl) once more 20 µl of derivatisation reagent with a higher concentration of the catalyst NH_4I (2%).

If we have excluded all above mentioned factors for the high TEST/EPIT ratio we start with the confirmation of the sample.

Confirmation of suspicious TEST/EPIT samples

Our procedure for the confirmation of samples with high TEST/EPIT ratios was exactly described by NOLTEERNSTING et al. (7).

The most important points are:

Reproducibility

To examine the reproducibility of the method, we prepare three aliquots of the sample which are injected twice. The variation coefficient of the TEST/EPIT ratios should be better than 5%. The mean of the TEST/EPIT values of the replicates minus three times the standard deviation should result in a value higher than 6.

Correction with deuterated standards

For the correction of the ratios TEST/EPIT the internal standards d3-TEST/d3-EPIT 6:1 are added to each sample.

Full scan spectrum of TEST and EPIT

Additional to the 3 aliquots we prepare one aliquot without internal standard to achieve full scan spectra of TEST and EPIT. This is done to show, that no other substance is coeluted with TEST or EPIT.

Increased urine volume

The used urine volume is increased to achieve a good GC signal especially for EPIT.

Separation of the free fraction

Before the hydrolysis, the free steroids are separated by extraction with ether. By this step, we prevent false positive results by unconjugated, bacterial produced, TEST (5).

Heating of the buffer

To avoid testosterone producing side activities from the phosphate buffer (8) during the hydrolysis, we boil the phosphate buffer for several minutes before the use.

*Hydrolysis with β -glucuronidase from *E.coli**

For the hydrolysis of the glucuronides we only use β -glucuronidase from *E. coli*, because we have never observed testosterone producing side activities in this enzyme preparation. Such activities can be found in the β -glucuronidase/ aylsulfatase of *Helix Pomatia* preparations (9).

n-pentane extraction

After hydrolysis the extraction of the steroids is performed with n-pentane instead of tert. butylmethyl ether. This is an additional clean up step to reduce the biological background for the detection of TEST and EPIT (10).

Changed MS parameters

For the MS detection is used a SIM method with only 5 ions. The molecular ions of the bis-TMS derivatives of TEST, EPIT, d3TEST and d3EPIT are registered with dwell times of 200 msec (7).

Measurement of LH, FSH and HCG

As proposed by KICMAN et al.(11) and COWAN et al.(12) we analyse also the gonadotropines LH, FSH and HCG. Of most importance is the ratio LH/TEST.

Measurement of ethanol

Several studies have shown that the application of ethanol may increase the TEST/EPIT ratio and decrease the AND/TEST ratio (13). Additionally we have found, that these changes of the steroid profile are always connected with the presence of ethanol in urine (13). Therefore we analyse samples with elevated TEST/EPIT ratios also for ethanol by Headspace/GC.

If we find ethanol, we stop the follow up protocol and don't give the sample positive. Until now we observed such cases only in Out of Competition Controls.

If the TEST/EPIT ratio > 6 is confirmed and the additional analyses are performed, we continue with the following steps.

Information of the Federation and request for further data

We inform the federation about the high TEST/EPIT ratio and ask for retrospective (code numbers of former dope controls) or prospective data (further dope controls) . For retrospective data, which are archived in other laboratories, we recommend the federation to provide the information listed in the formsheet for high TEST/EPIT values (Fig. 1). For the decision making process, we need at least data from 4 samples of the same athlete. The statistical evaluation of the data is performed as presented in the following chapter

If the retrospective or prospective data are not sufficient for the decision (e.g. not enough data, strong variation of the data), an endocrinological study is performed.

Remarks

Fig. 1: Formsheets for collection of data from other laboratories.

Endocrinological study (ES)

The aim of an ES is to calculate the subject based reference range for the TEST/EPIT ratio and the normal variation of the other TEST related steroid ratios. The basis for the judgement of the results is our knowledge about the stability of steroidprofile parameters in rest and exercise (14, 15, 16). The decision, positive or negative for the suspicious sample, is based upon a comparison of the steroidprofile values of the suspicious sample and the values of the ES.

The ES takes 2 days .During this time the athlete lives near by the laboratory. He can keep normal nutrition and training. The application of ethanol is not permitted.

Procedure

- Information of athlete about the aim and the procedure of the ES.
- Answering of a questionnaire (see Fig. 2)
- Collection of all urine fractions in a time period of at least 48 hours (ca. 13 - 15 samples according to a collection schedule (see Fig. 3).
At least 5 urine collections have to take place under observation of a member of the laboratory staff.
- Single blood sample collection (10 ml) performed by medical staff.

Analysis

| <i>Parameter</i> | <i>Single parameter</i> | <i>Analysentechnik</i> |
|--|--|------------------------|
| Steroidprofile parameters in urine (concentrations, excretion rates, ratios) | Glucuronides of androsterone, etiocholanolone, testosterone, epitestosterone, 5 α -androstan-3 α ,17 β -diol, 5 β -androstan-3 α ,17 β -diol, dihydrotestosterone, tetrahydrocortisol, 11 β -hydroxyandrosterone, 11 β -hydroxyetiocholanolone, pregnandiol, pregnantriol | GC/MSD |
| Peptide hormones in urine | LH, FSH, HCG | Enzymimmunoassay |
| Blood parameters | Testosterone, 17 α -hydroxyprogesterone (eventually esters of testosterone) | GC/HRMS |

Evaluation

- Statistical evaluation of the steroidprofile parameters and of the peptide hormone values (mean, standard deviation, coefficient of variation) for the determination of the individual reference ranges.
- Comparison of the values of the ES with the values of the suspicious sample.
- Comparison of the values of the ES with population based reference ranges.

Data evaluation of endocrinological studies or longitudinal studies

In table 7 and 8 are presented the results of an endocrinological study of a male athlete with 12 samples. The coefficients of variation (cv in %) for the presented steroid ratios should be

within 10 % and 25 % (14,15,16). If we have higher variations, e.g. in longitudinal studies with only 3 or 4 samples, we cannot calculate the subject based reference range for the TEST/EPIT ratio. For the ratio TEST/LH we observe always variations higher than 20%.

Tab. 7: Results of an ES. Concentrations of endogenous steroids.

| # | time | AND [ng/ml] | ETIO [ng/ml] | EPIT [ng/ml] | TEST [ng/ml] |

| 10 | 22:00 | 5,7 | 52,0 | 330,4 | 0,8 | 6,7 | 24,0 |
| 11 | 07:35 | 6,1 | 56,7 | 392,8 | 0,8 | 5,8 | 21,4 |
| 12 | 10:45 | 6,9 | 45,2 | 340,7 | 0,8 | 6,4 | 40,8 |
| mean | | 5,7 | 60,2 | 363,7 | 0,8 | 5,5 | 40,0 |
| stdev | | 0,9 | 13,1 | 50,2 | 0,1 | 2,5 | 19,9 |
| cv % | | 15,9 | 21,7 | 13,8 | 8,9 | 46,2 | 49,7 |

From mean and standard deviation (stdev) of the corrected TEST/EPIT ratios we calculate the limits of the subjected based reference range according to the formula (17):

- upper limit of subject based reference range = mean + 3 x stdev
- lower limit of subject based reference range = mean - 3 x stdev

In figure 4 are presented the single TEST/EPIT values of an ES and the corresponding reference limits

Fig. 4: TEST/EPIT values of an ES and corresponding limits of the subject based reference range (see table 8).

Blood samples in the ES

During the ES we take 10 ml of blood. We take this sample to receive additional TEST related information, e.g. about the ratio TEST/17 α - hydroxyprogesteron. The analysis is performed according to the GC/HRMS method described by HORNING et al. (18).

With this blood sample we have also the possibility, to prove an application of TEST during the ES by the detection of TEST-esters in the plasma.

Ketoconazole Test during the ES

A Ketoconazole test is an effective method for the differentiation between a natural elevated TEST/EPIT and a TEST abuse by an athlete (19). Such a test may be useful to detect a TEST application during the ES. But because of possible health risks by side effects of this drug, we hesitate to perform this test.

Interpretation of the results of an ES or a longitudinal study and recommendation to the federation

If the TEST/EPIT values and the other TEST related ratios of the suspicious samples lie within the subject based reference range and the variations of the ES values, we recommend to give the sample negative. In this case, we have a natural elevated TEST/EPIT ratio. The comparison of the ES values with the population based reference ranges allows to recognize the reason for the increased TEST/EPIT ratio. Most often a low EPIT concentration is responsible for the natural elevated TEST/EPIT ratio. Such a case is presented in tables 7 and 8. A low EPIT case is characterised by the following parameters:

- Concentration of EPIT near or outside the lower limit of the reference range
- Ratio AND/EPIT near or outside the upper limit of the reference range
- Ratio AND/TEST near the mean and median of this parameter
- Concentration of TEST near the mean and median of this parameter.

If we have a low EPIT case, we recommend to the federation to give a certification (naturally elevated T/E ratio) to the athlete. The certification should have the following consequences: In case a laboratory shows a "positive " result for TEST related parameters, the Antidoping Commission of the federation should be informed at once and before disciplinary measures be taken against the athlete. The decision positive or negative should be made only after the comparison of the suspicious values with the archived values of the athlete.

Shah

June 21, 2001

To: Clients of the UCLA Olympic Laboratory

Regarding: **Carbon Isotope Ratio measurements, Update 3**

This letter is to update you on our carbon isotope ratio method and to explain the wording we use in our current reports.

DIOL ASSAY

Requests: Currently when you request a CIR analysis we perform the "Diol" assay. The procedure is to request a CIR analysis by fax or email and to provide the sample number. We will check the original data on the sample and determine if the analysis is likely to be successful. If not, we will advise you that we do not believe the analysis will be successful and we may suggest an alternative approach. In order to enhance our understanding of the analysis we also ask that you give us all sample numbers of prior samples from the same athlete that were analyzed at UCLA.

The "Diol" assay determines the carbon isotope ratio (delta value) of two diol metabolites of testosterone which we refer to as M1 and M2, and one metabolite of a testosterone precursor (Pdiol). [See the metabolic map attached.] The assay determines the ratio of $^{13}\text{C}/^{12}\text{C}$ for each of these three steroids. The units are usually called "delta units". In addition to the delta values for these steroids, two other types of measurements are calculated. The first is the ratio of the metabolites to the precursor. Two ratios are calculated: M1/Pdiol and M2/Pdiol. The second is the difference between the metabolites and the Pdiol: M1 Pdiol and M2-Pdiol.

Endogenous reference compound: The Pdiol serves as an endogenous reference compound (ERC). Since it is a metabolite of a precursor (see map) in the testosterone metabolic scheme, its delta value does not change when testosterone is administered. In the typical positive case, the delta values of M1 and M2 are low and the delta value of Pdiol is within the normal range. In negative cases, all three diols have similar delta values. The reporting terminology will be: Positive, Negative, or Indeterminate.

A **POSITIVE** report means that the delta values for both M1 and M2 are at least three standard deviation (SD) units less than the mean (average) of a group of 73 normal males, and the delta value for Pdiol is within 3 SD of the mean of normal males. In addition the two ratios (M1/Pdiol and M2/Pdiol) and the two differences (M1-Pdiol and M2-Pdiol) are more than 3 SD from the range of normal values. These criteria are very conservative because all must be met for the sample to be declared positive.

A **NEGATIVE** report means that all three delta values, the two difference scores, and the two ratios are within the normal range.

An **INDETERMINATE** report means that we were not able to obtain definitive data. The most common reasons for this are insufficient sample volume and low concentrations of the steroids. Since there are several criteria for a positive report, it is also possible that a sample will have one ratio and one difference score that are normal and the other ratio and difference score will be abnormal. Other combinations of results are possible. Based on our current understanding of the theory underlying CIR measurements, we believe that in these mixed cases that we classify as indeterminate, some of the molecules of M1 or M2 are derived from pharmaceutical testosterone (or another exogenous steroid which is metabolized to

testosterone) and some of the molecules are from natural (endogenous) testosterone. This is expected when the body contains a mixture of pharmaceutical and natural testosterone and metabolites. This situation is likely to occur at the later times in the curve that relates delta values to time since drug administration. As our clients gain further understanding of the CIR analysis, you may have other opinions about how we report mixed cases.

SAMPLES FROM OTHER LABORATORIES

Occasionally we are asked to perform a CIR analysis on a sample that was originally processed at another sample. We are not comfortable with this for four reasons: 1) we do not know the details of handling and storage of the sample in the other laboratory, 2) we do not have any control over the chain-of-custody until the sample arrives at UCLA, 3) we do not have screening data (T/E, testosterone concentration, etc.) obtained at UCLA therefore we cannot adequately plan the analysis, and 4) we do not have control samples that were handled in the same way. We do not have any reason to believe that the CIR analysis is affected by storage conditions, time factors, or temperature nevertheless we cannot be absolutely certain that our in-house control data applies to such samples. In the future we will decline to perform the CIR analysis unless there is sufficient sample volume to perform both a steroid analysis and a CIR analysis.

ANDRO & ETIO ASSAY

Under certain circumstances we also offer the Andro & Etio assay. The advantages are that it is simpler to perform, less expensive, and it almost always yields definitive results. The disadvantage is that there is no PdIOL to serve as an ERC, therefore we are not able to calculate ratios or difference scores. Most clients seem to prefer the DIOL assay, however we suspect that in the future the Andro&Etio assay will be developed to the point where the lack of an ERC will not be a disadvantage. At this time we recommend the "diol" assay. Occasionally we will advise you that it is not possible to perform the DIOL assay and that the only CIR option is the Andro & Etio assay.

GENDER

At the present time we do not recommend performing the CIR analysis on samples from females. If you still wish to have the analysis we will determine if it is feasible to proceed based on the existing data from the athlete.

EPITESTOSTERONE

We have been working on a CIR assay for epitestosterone and we have recently presented our findings at a national meeting. There is no peer reviewed publication at this time and it will take about a year to prepare a manuscript and get it published. Nevertheless, at your request we will conduct the epitestosterone analysis on urine samples reported "epitestosterone > 200 ng/ml".

TURN-AROUND-TIME

In an attempt to keep the costs down we are performing the analyses one week per month. Typically this is the fourth week of the month. It takes about a week to complete the analysis, calculate the results, and the issue the report.

INTRODUCTION

THE PURPOSE, SCOPE AND ORGANIZATION OF THE WORLD ANTI-DOPING PROGRAM AND THE *CODE*

The purposes of the World Anti-Doping Program and the *Code* are:

- To protect the *Athletes'* fundamental right to participate in doping-free sport and thus promote health, fairness and equality for *Athletes* worldwide; and
- To ensure harmonized, coordinated and effective anti-doping programs at the international and national level with regard to detection, deterrence and prevention of doping.

THE WORLD ANTI-DOPING PROGRAM

The World Anti-Doping Program encompasses all of the elements needed in order to ensure optimal harmonization and best practice in international and national anti-doping programs. The main elements are:

Level 1: The *Code*

Level 2: *International Standards*

Level 3: Models of Best Practice

THE *CODE*

The *Code* is the fundamental and universal document upon which the World Anti-Doping Program in sport is based. The purpose of the *Code* is to advance the anti-doping effort through universal harmonization of core anti-doping elements. It is intended to be specific enough to achieve complete harmonization on issues where uniformity is required, yet general enough in other areas to permit flexibility on how agreed upon anti-doping principles are implemented.

INTERNATIONAL STANDARDS

International Standards for different technical and operational areas within the anti-doping program will be developed in consultation with the *Signatories* and governments and approved by WADA. The purpose of the *International Standards* is harmonization among *Anti-Doping Organizations* responsible for specific technical and operational parts of the anti-doping programs. Adherence to the *International Standards* is mandatory for compliance with the *Code*. The *International Standards* may be revised from time to time by the WADA Executive Committee after reasonable consultation with the *Signatories* and governments. Unless provided otherwise in the *Code*, *International Standards* and all revisions shall become effective on the date specified in the *International Standard* or revision.

MODELS OF BEST PRACTICE

Models of Best Practice based on the *Code* will be developed to provide state of the art solutions in different areas of anti-doping. The Models will be recommended by WADA and made available to *Signatories* upon request but will not be mandatory. In addition to providing models of anti-doping documentation, WADA will also make some training assistance available to the *Signatories*.

International Standards Comment: *International Standards* will contain much of the technical detail necessary for implementing the *Code*. This would include, for example, the detailed requirements for Sample collection, laboratory analysis and laboratory accreditation currently found in the Olympic Movement Anti-Doping Code 1999 ("OMADC"). *International Standards*, while expressly incorporated into the *Code* by reference, will, in consultation with the *Signatories* and governments, be developed by experts and set forth in separate technical documents. It is

important that the technical experts be able to make timely changes to the *International Standards* without requiring any amendment of the *Code* or individual stakeholder rules and regulations.

All applicable *International Standards* will be in place by January 1, 2004.

Models of Best Practice Comment: WADA will prepare model anti-doping rules and regulations tailored to the needs of each of the major groups of *Signatories* (e.g., *International Federations* for individual sports,

FUNDAMENTAL RATIONALE FOR THE WORLD ANTI-DOPING CODE

Anti-doping programs seek to preserve what is intrinsically valuable about sport. This intrinsic value is often referred to as "the spirit of sport"; it is the essence of Olympism: it is how we play true. The spirit of sport is the celebration of the human spirit, body and mind, and is characterized by the following values:

- Ethics, fair play and honesty.
- Health.
- Excellence in performance.
- Character and education.
- Fun and joy.
- Teamwork.
- Dedication and commitment.
- Respect for rules and laws.
- Respect for self and other participants.
- Courage.
- Community and solidarity.

Doping is fundamentally contrary to the spirit of sport.

International Federations for team sports, *National Anti-Doping Organizations*, etc.). These model rules and regulations will conform with and be based on the *Code*, will be state of the art examples of best practices and will contain all of the detail (including reference to *International Standards*) necessary to conduct an effective anti-doping program.

These model rules and regulations will provide alternatives from which stakeholders may select. Some stakeholders may choose to adopt the model rules and regulations and other models of best practices verbatim. Others may decide to adopt the models with modifications. Still other stakeholders may choose to develop

their own rules and regulations consistent with the general principles and specific requirements set forth in the *Code*.

Other model documents for specific parts of the anti-doping work may be developed based on generally recognized stakeholder needs and expectations. This could include models for national anti-doping programs, results management, Testing (beyond the specific requirements set forth in the *International Standard for Testing*), education programs, etc. All Models of Best Practice will be reviewed and approved by WADA before they are included in the World Anti-Doping Program.

PART ONE

DOPING CONTROL

INTRODUCTION

Part One of the *Code* sets forth specific anti-doping rules and principles that are to be followed by organizations responsible for adopting, implementing or enforcing anti-doping rules within their authority - - e.g., the International Olympic Committee, International Paralympic Committee, International Federations, *Major Event Organizations*, and *National Anti-Doping Organizations*. All of these organizations are collectively referred to as *Anti-Doping Organizations*.

Part One of the *Code* does not replace, or eliminate the need for, comprehensive anti-doping rules adopted by each of these *Anti-Doping Organizations*. While some provisions of Part One of the *Code* must be incorporated essentially verbatim by each *Anti-Doping Organization* in its own anti-doping rules, other provisions of Part One establish mandatory guiding principles that allow flexibility in the formulation of rules by each *Anti-Doping Organization* or establish requirements that must be followed by each *Anti-Doping Organization* but need not be repeated in its own anti-doping rules. The following Articles, as applicable to the scope of anti-doping activity which the *Anti-Doping Organization* performs, must be incorporated into the rules of each *Anti-Doping Organization* without any substantive changes (allowing for necessary non-substantive editing

Introduction Comment: For example it is critical to harmonization that all Signatories base their decisions on the same list of anti-doping rule violations, the same burdens of proof and impose the same Consequences for the same anti-doping rule violations. These substantive rules must be the same whether a hearing takes place before an International Federation, at the national level or before CAS. On the other hand, it is not necessary for effective harmonization to force all Signatories to use one single results management and hearing process.

At present, there are many different, yet equally effective processes for results management and hearings within different International Federations and different national bodies. The Code does not require absolute uniformity in results management and hearing procedures; it does, however, require that the diverse approaches of the Signatories satisfy principles stated in the Code.

With respect to Article 13, subpart 13.2.2 is not included in the provisions required to be adopted essentially

changes to the language in order to refer to the organization's name, sport, section numbers, etc.): Articles 1 (Definition of Doping), 2 (Anti-Doping Rule Violations), 3 (Proof of Doping), 9 (Automatic *Disqualification* of Individual Results), 10 (Sanctions on Individuals), 11 (*Consequences* to Teams), 13 (Appeals) with the exception of 13.2.2, 17 (Statute of Limitations) and Definitions.

Anti-doping rules, like competition rules, are sport rules governing the conditions under which sport is played. *Athletes* accept these rules as a condition of participation. Anti-doping rules are not intended to be subject to or limited by the requirements and legal standards applicable to criminal proceedings or employment matters. The policies and minimum standards set forth in the *Code* represent the consensus of a broad spectrum of stakeholders with an interest in fair sport and should be respected by all courts and adjudicating bodies.

Participants shall be bound to comply with the anti-doping rules adopted in conformance with the *Code* by the relevant *Anti-Doping Organizations*. Each *Signatory* shall establish rules and procedures to ensure that all *Participants* under the authority of the *Signatory* and its member organizations are informed of and agree to be bound by anti-doping rules in force of the relevant *Anti-Doping Organizations*.

verbatim, as 13.2.2 establishes mandatory guiding principles that allow some flexibility in the formulation of rules by the Anti-Doping Organization.

Participants Comment: By their participation in sport, Athletes are bound by the competitive rules of their sport. In the same manner, Athletes and Athlete Support Personnel should be bound by anti-doping rules based on Article 2 of the Code by virtue of their agreements for membership, accreditation, or participation in sports organizations or sports events subject to the Code. Each Signatory, however, shall take the necessary steps to ensure that all Athletes and Athlete Support Personnel within its authority are bound by the relevant Anti-Doping Organization's anti-doping rules.

ARTICLE 1: DEFINITION OF DOPING

Doping is defined as the occurrence of one or more of the anti-doping rule violations set forth in Article 2.1 through Article 2.8 of the Code.

ARTICLE 2: ANTI-DOPING RULE VIOLATIONS

The following constitute anti-doping rule violations:

2.1 The presence of a *Prohibited Substance* or its *Metabolites* or *Markers* in an *Athlete's* bodily *Specimen*.

2.1.1 It is each *Athlete's* personal duty to ensure that no *Prohibited Substance* enters his or her body. *Athletes* are responsible for any *Prohibited Substance* or its *Metabolites* or *Markers* found to be present in their bodily *Specimens*. Accordingly, it is not necessary that intent, fault, negligence or knowing *Use* on the *Athlete's* part be demonstrated in order to establish an anti-doping violation under Article 2.1.

2 Comment: The purpose of Article 2 is to specify the circumstances and conduct which constitute violations of anti-doping rules. Hearings in doping cases will proceed based on the assertion that one or more of these specific rules have been violated. Most of the circumstances and conduct on this list of violations can be found in some form in the OMADC or other existing anti-doping rules.

2.1.1 Comment: For purposes of anti-doping violations involving the presence of a *Prohibited Substance* (or its *Metabolites* or *Markers*), the Code adopts the rule of strict liability which is found in the OMADC and the vast majority of existing anti-doping rules. Under the strict liability principle, an anti-doping rule violation occurs whenever a *Prohibited Substance* is found in an *Athlete's* bodily *Specimen*. The violation occurs whether

or not the *Athlete* intentionally or unintentionally used a *Prohibited Substance* or was negligent or otherwise at fault. If the positive *Sample* came from an *In-Competition* test, then the results of that *Competition* are automatically invalidated (Article 9 (Automatic Disqualification of Individual Results)). However, the *Athlete* then has the possibility to avoid or reduce sanctions if the *Athlete* can demonstrate that he or she was not at fault or significant fault (Article 10.5 (Elimination or Reduction of Period of Ineligibility Based on Exceptional Circumstances)).

The strict liability rule for the finding of a *Prohibited Substance* in an *Athlete's* *Specimen*, with a possibility that sanctions may be modified based on specified criteria, provides a reasonable balance between effective anti-doping

2.1.2 Excepting those substances for which a quantitative reporting threshold is specifically identified in the *Prohibited List*, the detected presence of any quantity of a *Prohibited Substance* or its *Metabolites* or *Markers* in an *Athlete's Sample* shall constitute an anti-doping rule violation.

2.1.3 As an exception to the general rule of Article 2.1, the *Prohibited List* may establish special criteria for the evaluation of *Prohibited Substances* that can also be produced endogenously.

enforcement for the benefit of all "clean" *Athletes* and fairness in the exceptional circumstance where a *Prohibited Substance* entered an *Athlete's* system through no fault or negligence on the *Athlete's* part. It is important to emphasize that while the determination of whether the anti-doping rule has been violated is based on strict liability, the imposition of a fixed period of ineligibility is not automatic.

The rationale for the strict liability rule was well stated by the Court of Arbitration for Sport in the case of Quigley v. UIT.

"It is true that a strict liability test is likely in some sense to be unfair in an individual case, such as that of Q., where the *Athlete* may have taken medication as the result of mislabeling or faulty advice for which he or she is not responsible - particularly in the circumstances of sudden illness in a foreign country. But it is also in some sense "unfair" for an *Athlete* to get food poisoning on the eve of an important competition. Yet in neither case will the rules of the competition be altered to undo the unfairness. Just as the competition will not be postponed to await the *Athlete's* recovery, so the prohibition of banned substances will not be lifted in recognition of its accidental absorption. The vicissitudes of competition, like those of life generally,

may create many types of unfairness whether by accident or the negligence of unaccountable Persons, which the law cannot repair.

Furthermore, it appears to be a laudable policy objective not to repair an accidental unfairness to an individual by creating an intentional unfairness to the whole body of other competitors. This is what would happen if banned performance-enhancing substances were tolerated when absorbed inadvertently. Moreover, it is likely that even intentional abuse would in many cases escape sanction for lack of proof of guilty intent. And it is certain that a requirement of intent would invite costly litigation that may well cripple federations - particularly those run on modest budgets - in their fight against doping."

2.1.3 Comment: For example, the *Prohibited List* might provide that a T/E ratio greater than 6:1 is doping unless a longitudinal analysis of prior or subsequent test results by the Anti-Doping Organization demonstrates a naturally elevated ratio or the *Athlete* otherwise establishes that the elevated ratio is the result of a physiological or pathological condition.

2.2 Use or Attempted Use of a Prohibited Substance or a Prohibited Method.

2.2.1 The success or failure of the Use of a Prohibited Substance or Prohibited Method is not material. It is sufficient that the Prohibited Substance or Prohibited Method was Used or Attempted to be Used for an anti-doping rule violation to be committed.

2.3 Refusing, or failing without compelling justification, to submit to Sample collection after notification as authorized in applicable anti-doping rules or otherwise evading Sample collection.

2.2.1 Comment: The prohibition against "Use" has been expanded from the text in the OMADC to include Prohibited Substances as well as Prohibited Methods. With this inclusion there is no need to specifically delineate "admission of Use" as a separate anti-doping rule violation. "Use" can be proved, for example, through admissions, third party testimony or other evidence.

Demonstrating the "Attempted Use" of a Prohibited Substance requires proof of intent on the Athlete's part. The fact that intent may be required to prove this particular anti-doping rule violation does not undermine the strict liability principle established for violations of Article 2.1 and Use of a Prohibited Substance or Prohibited Method.

An Athlete's Out-of-Competition Use of a Prohibited Substance that is not prohibited Out-of-Competition would not constitute an anti-doping rule violation.

2.3 Comment: Failure or refusal to submit to Sample collection after notification is prohibited in almost all existing anti-doping rules. This Article expands the typical rule to include "otherwise evading Sample collection" as prohibited conduct. Thus, for example, it would be an anti-doping rule violation if it were established that an Athlete was hiding from a Doping Control official who was attempting to conduct a test. A violation of "refusing or failing to submit to Sample collection" may be based on either intentional or negligent conduct of the Athlete, while "evading" Sample collection contemplates intentional conduct by the Athlete.

2.4 Violation of applicable requirements regarding Athlete availability for Out-of-Competition Testing including failure to provide required whereabouts information and missed tests which are declared based on reasonable rules.

2.5 Tampering, or Attempting to tamper, with any part of Doping Control.

2.6 Possession of Prohibited Substances and Methods:

2.6.1 Possession by an Athlete at any time or place of a substance that is prohibited in Out-of-Competition Testing or a Prohibited Method unless the Athlete establishes that the Possession is pursuant to a therapeutic use exemption granted in accordance with Article 4.4 (Therapeutic Use) or other acceptable justification.

2.6.2 Possession of a substance that is prohibited in Out-of-Competition Testing or a Prohibited Method by Athlete Support Personnel in connection with an Athlete, Competition or training, unless the Athlete Support Personnel establishes that the Possession is pursuant to a therapeutic use exemption granted to an Athlete in accordance with Article 4.4 (Therapeutic Use) or other acceptable justification.

2.4 Comment: Unannounced Out-of-Competition Testing is at the core of effective Doping Control. Without accurate Athlete location information such Testing is inefficient and sometimes impossible. This Article, which is not typically found in most existing anti-doping rules, requires Athletes that have been identified for Out-of-Competition Testing to be responsible for providing and updating information on their whereabouts so that they can be located for No Advance Notice Out-of-Competition Testing. The "applicable requirements" are set by the Athlete's International Federation and National

Anti-Doping Organization in order to allow some flexibility based upon varying circumstances encountered in different sports and countries. A violation of this Article may be based on either intentional or negligent conduct by the Athlete.

2.5 Comment: This Article prohibits conduct which subverts the Doping Control process but which would not be included in the typical definition of Prohibited Methods. For example, altering identification numbers on a Doping Control form during Testing or breaking the B Bottle at the time of B Sample analysis.

- 2.7** *Trafficking in any Prohibited Substance or Prohibited Method.*
- 2.8** Administration or Attempted administration of a *Prohibited Substance* or *Prohibited Method* to any *Athlete*, or assisting, encouraging, aiding, abetting, covering up or any other type of complicity involving an anti-doping rule violation or any *Attempted* violation.

ARTICLE 3: PROOF OF DOPING

3.1 Burdens and Standards of Proof.

The *Anti-Doping Organization* shall have the burden of establishing that an anti-doping rule violation has occurred. The standard of proof shall be whether the *Anti-Doping Organization* has established an anti-doping rule violation to the comfortable satisfaction of the hearing body bearing in mind the seriousness of the allegation which is made. This standard of proof in all cases is greater than a mere balance of probability but less than proof beyond a reasonable doubt. Where the *Code* places the burden of proof upon the *Athlete* or other *Person* alleged to have committed an anti-doping rule violation to rebut a presumption or establish specified facts or circumstances, the standard of proof shall be by a balance of probability.

3.2 Methods of Establishing Facts and Presumptions.

Facts related to anti-doping rule violations may be established by any reliable means, including admissions. The following rules of proof shall be applicable in doping cases:

3.1 Comment: This standard of proof required to be met by the *Anti-Doping Organization* is comparable to the standard which is applied in most countries to cases involving professional

misconduct. It has also been widely applied by courts and tribunals in doping cases. See, for example, the CAS decision in *N. J. Y. W. v. FINA*, CAS 98/208, 22 December 1998.

- 3.2.1** WADA-accredited laboratories are presumed to have conducted *Sample* analysis and custodial procedures in accordance with the *International Standard* for laboratory analysis. The *Athlete* may rebut this presumption by establishing that a departure from the *International Standard* occurred.

If the *Athlete* rebuts the preceding presumption by showing that a departure from the *International Standard* occurred, then the *Anti-Doping Organization* shall have the burden to establish that such departure did not cause the *Adverse Analytical Finding*.

- 3.2.2** Departures from the *International Standard* for *Testing* which did not cause an *Adverse Analytical Finding* or other anti-doping rule violation shall not invalidate such results. If the *Athlete* establishes that departures from the *International Standard* occurred during *Testing* then the *Anti-Doping Organization* shall have the burden to establish that such departures did not cause the *Adverse Analytical Finding* or the factual basis for the anti-doping rule violation.

3.2.1 Comment: The burden is on the *Athlete* to establish, by a preponderance of the evidence, a departure from the *International Standard*. If the *Athlete* does so, the

burden shifts to the *Anti-Doping Organization* to prove to the comfortable satisfaction of the hearing body that the departure did not change the test result.

ARTICLE 4: THE PROHIBITED LIST

4.1 Publication and Revision of the *Prohibited List*.

WADA shall, as often as necessary and no less often than annually, publish the *Prohibited List* as an *International Standard*. The proposed content of the *Prohibited List* and all revisions shall be provided in writing promptly to all *Signatories* and governments for comment and consultation. Each annual version of the *Prohibited List* and all revisions shall be distributed promptly by WADA to each *Signatory* and government and shall be published on WADA's website, and each *Signatory* shall take appropriate steps to distribute the *Prohibited List* to its members and constituents. The rules of each *Anti-Doping Organization* shall specify that, unless provided otherwise in the *Prohibited List* or a revision, the *Prohibited List* and revisions shall go into effect under the *Anti-Doping Organization's* rules three months after publication of the *Prohibited List* by WADA without requiring any further action by the *Anti-Doping Organization*.

4.2 *Prohibited Substances and Prohibited Methods* Identified on the *Prohibited List*.

The *Prohibited List* shall identify those *Prohibited Substances and Prohibited Methods* which are prohibited as doping at all times (both *In-Competition* and *Out-of-*

4.1 Comment: The *Prohibited List* will be revised and published on an expedited basis whenever the need arises. However, for the sake of predictability, a new list will be published every year whether or not changes have been made. The virtue of the IOC practice of publishing a new list every January is that it avoids confusion over which list is the most current. To address this issue, WADA will always have the most current *Prohibited List* published on its website.

It is anticipated that revised anti-doping rules adopted by *Anti-Doping Organizations* pursuant to the Code will not go into effect until January 1, 2004 with the publication of the first *Prohibited List* adopted by WADA. The OMADC will continue to be applicable until the Code is accepted by the International Olympic Committee.

4.2 Comment: There will be one *Prohibited List*. The substances which are prohibited at all times

Competition) because of their potential to enhance performance in future *Competitions* or their masking potential and those substances and methods which are prohibited *In-Competition* only. Upon the recommendation of an International Federation, the *Prohibited List* may be expanded by WADA for that particular sport. *Prohibited Substances and Prohibited Methods* may be included in the *Prohibited List* by general category (e.g., anabolic agents) or by specific reference to a particular substance or method.

4.3 Criteria for Including Substances and Methods on the *Prohibited List*.

WADA shall consider the following criteria in deciding whether to include a substance or method on the *Prohibited List*.

4.3.1 A substance or method shall be considered for inclusion on the *Prohibited List* if WADA determines that the substance or method meets any two of the following three criteria:

4.3.1.1 Medical or other scientific evidence, pharmacological effect or experience that the substance or method has the potential to enhance or enhances sport performance;

would include masking agents and those substances which, when used in training, may have long term performance enhancing effects such as anabolics. All substances and methods on the *Prohibited List* are prohibited *In-Competition*. This distinction between what is tested for *In-Competition* and what is tested for *Out-of-Competition* is carried over from the OMADC. There will be only one document called the "*Prohibited List*." WADA may add additional substances or methods to the *Prohibited List* for particular sports (e.g. the inclusion of beta-blockers for

shooting) but this will also be reflected on the single *Prohibited List*. Having all *Prohibited Substances* on a single list will avoid some of the current confusion related to identifying which substances are prohibited in which sports. Individual sports are not permitted to seek exemption from the basic list of *Prohibited Substances* (e.g. eliminating anabolics from the *Prohibited List* for "mind sports"). The premise of this decision is that there are certain basic doping agents which anyone who chooses to call himself or herself an Athlete should not take.

4.3.1.2 Medical or other scientific evidence, pharmacological effect, or experience that the *Use* of the substance or method represents an actual or potential health risk to the *Athlete*;

4.3.1.3 WADA's determination that the *Use* of the substance or method violates the spirit of sport described in the Introduction to the *Code*.

4.3.2 A substance or method shall also be included on the *Prohibited List* if WADA determines there is medical or other scientific evidence, pharmacological effect or experience that the substance or method has the potential to mask the *Use* of other *Prohibited Substances* and *Prohibited Methods*.

4.3.2 Comment: A substance shall be considered for inclusion on the *Prohibited List* if the substance is a masking agent or meets two of the following three criteria: (1) it has the potential to enhance or enhances sport performance; (2) it represents a potential or actual health risk; or (3) it is contrary to the spirit of sport. None of the three criteria *alone* is a sufficient basis for adding a substance to the *Prohibited List*. Using the potential to enhance performance as the sole criteria would include, for example, physical and mental training, red meat, carbohydrate loading and training at

altitude. Risk of harm would include smoking. Requiring all three criteria would also be unsatisfactory. For example the use of genetic transfer technology to dramatically enhance sport performance should be prohibited as contrary to the spirit of sport even if it is not harmful. Similarly, the potentially unhealthy abuse of certain substances without therapeutic justification based on the mistaken belief they enhance performance is certainly contrary to the spirit of sport regardless of whether the expectation of performance enhancement is realistic.

4.3.3 WADA's determination of the *Prohibited Substances* and *Prohibited Methods* that will be included on the *Prohibited List* shall be final and shall not be subject to challenge by an *Athlete* or other *Person* based on an argument that the substance or method was not a masking agent or did not have the potential to enhance performance, represent a health risk, or violate the spirit of sport.

4.4 Therapeutic Use

WADA shall adopt an *International Standard* for the process of granting therapeutic use exemptions.

Each International Federation shall ensure, for *International-Level Athletes* or any other *Athlete* who is

4.3.3 Comment: The question of whether a substance meets the criteria in Article 4.3 (Criteria for Including Substances and Methods on the *Prohibited List*) in a particular case cannot be raised as a defense to an anti-doping rule violation. For example, it cannot be argued that the *Prohibited Substance* detected would not have been performance enhancing in that particular sport. Rather, doping occurs when a substance on the *Prohibited List* is found in an *Athlete's* bodily Specimen. The same principle is found in the OMADC.

4.4 Comment: It is important that the processes for granting therapeutic use exemptions become more harmonized. *Athletes* who use medically prescribed *Prohibited Substances* may be subject to sanctioning unless they have previously obtained a therapeutic use exemption. However, currently many sporting bodies have no rules permitting therapeutic use exemptions; others follow unwritten policies; and only a few have written policies incorporated into their anti-doping rules. This Article seeks to harmonize the basis upon which therapeutic use exemptions will be

granted and gives responsibility for granting or denying exemptions to the International Federations for *International-Level Athletes* and to the National Anti-Doping Organizations for national-level *Athletes* (that are not also *International-Level Athletes*) and other *Athletes* subject to Doping Control under the *Code*.

Examples of commonly prescribed *Prohibited Substances* which might be specifically addressed in the *International Standard* for therapeutic use exemptions are medications prescribed for acute severe asthma and inflammatory bowel disease. When a therapeutic use exemption has been denied or granted in contravention of the *International Standard*, that decision may be submitted to WADA for review as provided in the *International Standard* and thereafter appealed as provided in Article 13.3 (Appeals). If the granting of a therapeutic use exemption is reversed, the reversal shall not apply retroactively and shall not disqualify the *Athlete's* results during the time that the therapeutic use exemption was in effect.

entered in an *International Event*, that a process is in place whereby *Athletes* with documented medical conditions requiring the *Use* of a *Prohibited Substance* or a *Prohibited Method* may request a therapeutic use exemption. Each *National Anti-Doping Organization* shall ensure, for all *Athletes* within its jurisdiction that are not *International-Level Athletes*, that a process is in place whereby *Athletes* with documented medical conditions requiring the *Use* of a *Prohibited Substance* or a *Prohibited Method* may request a therapeutic use exemption. Such requests shall be evaluated in accordance with the *International Standard* on therapeutic use. International Federations and *National Anti-Doping Organizations* shall promptly report to WADA the granting of therapeutic use exemptions to any *International-Level Athlete* or national-level *Athlete* that is included in his or her *National Anti-Doping Organization's Registered Testing Pool*.

WADA, on its own initiative, may review the granting of a therapeutic use exemption to any *International-Level Athlete* or national-level *Athlete* that is included in his or her *National Anti-Doping Organization's Registered Testing Pool*. Further, upon the request of any such *Athlete* that has been denied a therapeutic use exemption, WADA may review such denial. If WADA determines that such granting or denial of a therapeutic use exemption did not comply with the *International Standard* for therapeutic use exemptions, WADA may reverse the decision.

4.5 Monitoring Program

WADA, in consultation with other *Signatories* and governments, shall establish a monitoring program regarding substances which are not on the *Prohibited List*, but which WADA wishes to monitor in order to detect patterns of misuse in sport. WADA shall publish, in advance of any *Testing*, the substances that will be monitored. Laboratories will report the instances of reported *Use* or detected presence of these substances to

WADA periodically on an aggregate basis by sport and whether the *Samples* were collected *In-Competition* or *Out-of-Competition*. Such reports shall not contain additional information regarding specific *Samples*. WADA shall make available to International Federations and *National Anti-Doping Organizations*, on at least an annual basis, aggregate statistical information by sport regarding the additional substances. WADA shall implement measures to ensure that strict anonymity of individual *Athletes* is maintained with respect to such reports. The reported use or detected presence of the monitored substances shall not constitute a doping violation.

ARTICLE 5: TESTING

5.1 Test Distribution Planning. *Anti-Doping Organizations* conducting *Testing* shall in coordination with other *Anti-Doping Organizations* conducting *Testing* on the same *Athlete* pool:

5.1.1 Plan and implement an effective number of *In-Competition* and *Out-of-Competition* tests. Each International Federation shall establish a *Registered Testing Pool* for *International-Level Athletes* in its sport, and each *National Anti-Doping Organization* shall establish a national *Registered Testing Pool* for *Athletes* in its country. The national-level pool shall include *International-Level Athletes* from that country as well as other national-level *Athletes*. Each International Federation and *National Anti-Doping Organization* shall plan and conduct *In-Competition* and *Out-of-Competition Testing* on its *Registered Testing Pool*.

5.1.2 Make *No Advance Notice Testing* a priority.

5.1.3 Conduct *Target Testing*.

5.1.3 Comment: *Target Testing* is specified because random *Testing*, or even weighted random *Testing*, does

not ensure that all of the appropriate *Athletes* will be tested. (For example, world class *Athletes*, *Athletes* whose

5.2 Standards for Testing

Anti-Doping Organizations conducting *Testing* shall conduct such *Testing* in conformity with the *International Standard for Testing*.

ARTICLE 6: ANALYSIS OF SAMPLES

Doping Control Samples shall be analyzed in accordance with the following principles:

6.1 Use of Approved Laboratories

Doping Control Samples shall be analyzed only in WADA-accredited laboratories or as otherwise approved by WADA. The choice of the WADA-accredited laboratory (or other method approved by WADA) used for the *Sample* analysis shall be determined exclusively by the *Anti-Doping Organization* responsible for results management.

6.2 Substances Subject to Detection

Doping Control Samples shall be analyzed to detect *Prohibited Substances* and *Prohibited Methods* identified on the *Prohibited List* and other substances as may be directed by WADA pursuant to Article 4.5 (Monitoring Program).

6.3 Research on Samples

No *Sample* may be used for any purpose other than the detection of substances (or classes of substances) or methods on the *Prohibited List*, or as otherwise identified

performances have dramatically improved over a short period of time. Athletes whose coaches have had other Athletes test positive, etc.).

Obviously, Target Testing must not be used for any purpose other than legitimate Doping Control. The Code makes it clear that Athletes have no right to expect that they will be tested only on a random basis. Similarly, it does not impose any reasonable suspicion or probable cause requirement for Target Testing.

5.2 Comment: The required methods and processes for the various types of In-Competition and Out-of-Competition Testing will be described in greater detail in the *International Standard for Testing*.

6.1 Comment: The phrase "or other method approved by WADA" is intended to cover, for example, mobile blood Testing procedures which WADA has reviewed and considers to be reliable.

by WADA pursuant to Article 4.5 (Monitoring Program), without the *Athlete's* written consent.

6.4 Standards for Sample Analysis and Reporting

Laboratories shall analyze *Doping Control Samples* and report results in conformity with the *International Standard* for laboratory analysis.

ARTICLE 7: RESULTS MANAGEMENT

Each *Anti-Doping Organization* conducting results management shall establish a process for the pre-hearing administration of potential anti-doping rule violations that respects the following principles:

7.1 Initial Review Regarding Adverse Analytical Findings

Upon receipt of an *A Sample Adverse Analytical Finding*, the *Anti-Doping Organization* responsible for results management shall conduct a review to determine whether: (a) an applicable therapeutic use exemption has been granted, or (b) there is any apparent departure from the *International Standards for Testing* or laboratory analysis that undermines the validity of the *Adverse Analytical Finding*.

7.2 Notification After Initial Review

If the initial review under Article 7.1 does not reveal an applicable therapeutic use exemption or departure that undermines the validity of the *Adverse Analytical Finding*,

7 Comment: Various of the Signatories have created their own approaches to results management for Adverse Analytical Findings. While the various approaches have not been entirely uniform, many have proven to be fair and effective systems for results management. The Code does not supplant each of the Signatories' results management systems. This Article does, however, specify basic principles in order to ensure the fundamental

fairness of the results management process which must be observed by each Signatory. The specific anti-doping rules of each Signatory shall be consistent with these basic principles.

7.2 Comment: The Athlete has a right to request a prompt B Sample analysis regardless of whether follow-up investigation may be required under Articles 7.3 or 7.4.

the *Anti-Doping Organization* shall promptly notify the *Athlete*, in the manner set out in its rules, of: (a) the *Adverse Analytical Finding*; (b) the anti-doping rule violated, or, in a case under Article 7.3, a description of the additional investigation that will be conducted as to whether there is an anti-doping rule violation; (c) the *Athlete's* right to promptly request the analysis of the B *Sample* or, failing such request, that the B *Sample* analysis may be deemed waived; (d) the right of the *Athlete* and/or the *Athlete's* representative to attend the B *Sample* opening and analysis if such analysis is requested; and (e) the *Athlete's* right to request copies of the A and B *Sample* laboratory documentation package which includes information as required by the *International Standard* for laboratory analysis.

7.3 Further Review of Adverse Analytical Finding Where Required by Prohibited List

The *Anti-Doping Organization* or other reviewing body established by such organization shall also conduct any follow-up investigation as may be required by the *Prohibited List*. Upon completion of such follow-up investigation, the *Anti-Doping Organization* shall promptly notify the *Athlete* regarding the results of the follow-up investigation and whether or not the *Anti-Doping Organization* asserts that an anti-doping rule was violated.

7.4 Review of Other Anti-Doping Rule Violations

The *Anti-Doping Organization* or other reviewing body established by such organization shall conduct any follow-up investigation as may be required under applicable anti-doping policies and rules adopted pursuant to the *Code* or which the *Anti-Doping Organization* otherwise considers appropriate. The *Anti-Doping Organization* shall promptly give the *Athlete* or other *Person* subject to sanction notice,

7.4 Comment: As an example, an *International Federation* typically

would notify the *Athlete* through the *Athlete's* national sports federation.

in the manner set out in its rules, of the anti-doping rule which appears to have been violated, and the basis of the violation.

7.5 Principles Applicable to Provisional Suspensions

A *Signatory* may adopt rules, applicable to any *Event* for which the *Signatory* is the ruling body or for any team selection process for which the *Signatory* is responsible, permitting *Provisional Suspensions* to be imposed after the review and notification described in Articles 7.1 and 7.2 but prior to a final hearing as described in Article 8 (Right to a Fair Hearing). Provided, however, that a *Provisional Suspension* may not be imposed unless the *Athlete* is given either: (a) an opportunity for a *Provisional Hearing* either before imposition of the *Provisional Suspension* or on a timely basis after imposition of the *Provisional Suspension*; or (b) an opportunity for an expedited hearing in accordance with Article 8 (Right to a Fair Hearing) on a timely basis after imposition of a *Provisional Suspension*.

If a *Provisional Suspension* is imposed based on an A *Sample Adverse Analytical Finding* and a subsequent B *Sample* analysis does not confirm the A *Sample* analysis, then the *Athlete* shall not be subject to any further disciplinary action and any sanction previously imposed shall be rescinded. In circumstances where the *Athlete* or the *Athlete's* team has been removed from a *Competition* and the subsequent B *Sample* analysis does not confirm the A *Sample* finding, if, without otherwise affecting the *Competition*, it is still possible for the *Athlete* or team to be reinserted, the *Athlete* or team may continue to take part in the *Competition*.

7.5 Comment: This Article continues to permit the possibility of a *Provisional Suspension* before a final decision at a hearing under Article 8 (Right to a Fair Hearing). *Provisional Suspensions* have been authorized in the OMADC and by the rules of many *International Federations*. However,

before a *Provisional Suspension* can be unilaterally imposed by an *Anti-Doping Organization*, the internal review specified in the *Code* must first be completed. In addition, a *Signatory* imposing a *Provisional Suspension* is required to give the *Athlete* an opportunity for a *Provisional Hearing*

ARTICLE 8: RIGHT TO A FAIR HEARING

Each *Anti-Doping Organization* with responsibility for results management shall provide a hearing process for any *Person* who is asserted to have committed an anti-doping rule violation. Such hearing process shall address whether an anti-doping violation was committed and, if so, the appropriate *Consequences*. The hearing process shall respect the following principles:

- a timely hearing;
- fair and impartial hearing body;
- the right to be represented by counsel at the *Person's* own expense;
- the right to be fairly and timely informed of the asserted anti-doping rule violation;
- the right to respond to the asserted anti-doping rule violation and resulting *Consequences*;

either before or promptly after the imposition of the Provisional Suspension, or an expedited final hearing under Article 8 promptly after imposition of the Provisional Suspension. The Athlete has a right to appeal under Article 13.2. As an alternative to the process for imposing a Provisional Suspension under this Article, the Anti-Doping Organization may always elect to forego a Provisional Suspension and proceed directly to the final hearing utilizing an expedited process under Article 8.

In the rare circumstance where the B Sample analysis does not confirm the A Sample finding, the Athlete that had been provisionally suspended will be

allowed, where circumstances permit, to participate in subsequent Competitions during the Event. Similarly, depending upon the relevant rules of the International Federation in a Team Sport, if the team is still in Competition, the Athlete may be able to take part in future Competitions.

8 Comment: This Article contains basic principles relative to ensuring a fair hearing for Persons asserted to have violated anti-doping rules. This Article is not intended to supplant each Signatory's own rules for hearings but rather to ensure that each Signatory provides a hearing process consistent with these principles.

- the right of each party to present evidence, including the right to call and question witnesses (subject to the hearing body's discretion to accept testimony by telephone or written submission);
- the *Person's* right to an interpreter at the hearing, with the hearing body to determine the identity, and responsibility for the cost, of the interpreter; and
- a timely, written, reasoned decision;

Hearings held in connection with *Events* may be conducted by an expedited process as permitted by the rules of the relevant *Anti-Doping Organization* and the hearing body.

ARTICLE 9: AUTOMATIC DISQUALIFICATION OF INDIVIDUAL RESULTS

An anti-doping rule violation in connection with an *In-Competition* test automatically leads to *Disqualification* of the individual result obtained in that *Competition* with all resulting consequences, including forfeiture of any medals, points and prizes.

The reference to CAS as an appellate body in Article 13 does not prevent a Signatory from also specifying CAS as the initial hearing body.

For example a hearing could be expedited on the eve of a major Event where the resolution of the anti-doping rule violation is necessary to determine the Athlete's eligibility to participate in the Event or during an Event where the resolution of the case will affect the validity of the Athlete's results or continued participation in the Event.

9 Comment: This principle is found in the OMADC. When an Athlete wins a gold medal with a Prohibited Substance in his or her system, that is unfair to the other Athletes in that Competition regardless of whether the gold medalist was at fault in any way. Only a "clean" Athlete should be allowed to benefit from his or her competitive results.

For Team Sports, see Article 11 (Consequences to Teams).

ARTICLE 10: SANCTIONS ON INDIVIDUALS

10.1 *Disqualification of Results in Event During which an Anti-Doping Rule Violation Occurs*

An anti-doping rule violation occurring during or in connection with an *Event* may, upon the decision of the ruling body of the *Event*, lead to *Disqualification* of all of the *Athlete's* individual results obtained in that *Event* with all consequences, including forfeiture of all medals, points and prizes, except as provided in Article 10.1.1.

10.1.1 If the *Athlete* establishes that he or she bears *No Fault or Negligence* for the violation, the *Athlete's* individual results in the other *Competitions* shall not be *Disqualified* unless the *Athlete's* results in *Competitions* other than the *Competition* in which the anti-doping rule violation occurred were likely to have been affected by the *Athlete's* anti-doping rule violation.

10.2 *Imposition of Ineligibility for Prohibited Substances and Prohibited Methods*

Except for the specified substances identified in Article 10.3, the period of *Ineligibility* imposed for a violation of Articles 2.1 (presence of *Prohibited Substance* or its *Metabolites* or

10.1 Comment: Whereas Article 9 (Automatic Disqualification of Individual Results) Disqualifies the result in a single Competition in which the Athlete tested positive (e.g., the 100 meter backstroke), this Article may lead to Disqualification of all results in all races during the Event (e.g., the FINA World Championships).

Factors to be included in considering whether to Disqualify other results in an Event might include, for example, the severity of the Athlete's anti-doping rule violation and whether the Athlete tested negative in the other Competitions.

10.2 Comment: Harmonization of sanctions has been one of the most discussed and debated areas of anti-doping. Arguments against requiring harmonization of sanctions are based on differences between sports including for example the following: in some sports the Athletes are professionals making a sizable income from the sport and in others the Athletes are true amateurs; in those sports where an Athlete's career is short (e.g. artistic gymnastics) a two year Disqualification has a much more significant effect on the Athlete than in sports where careers are traditionally

Markers). 2.2 (Use or Attempted Use of Prohibited Substance or Prohibited Method) and 2.6 (Possession of Prohibited Substances and Methods) shall be:

- First violation: Two (2) years' *Ineligibility*.
- Second violation: Lifetime *Ineligibility*.

However, the *Athlete* or other *Person* shall have the opportunity in each case, before a period of *Ineligibility* is imposed, to establish the basis for eliminating or reducing this sanction as provided in Article 10.5

10.3 *Specified Substances*

The *Prohibited List* may identify specified substances which are particularly susceptible to unintentional anti-doping rules violations because of their general availability in medicinal products or which are less likely to be successfully abused as doping agents. Where an *Athlete* can establish that the *Use* of such a specified

much longer (e.g. equestrian and shooting); in individual sports, the Athlete is better able to maintain competitive skills through solitary practice during Disqualification than in other sports where practice as part of a team is more important. A primary argument in favor of harmonization is that it is simply not right that two Athletes from the same country who test positive for the same Prohibited Substance under similar circumstances should receive different sanctions only because they participate in different sports. In addition, flexibility in sanctioning has often been viewed as an unacceptable opportunity for some sporting bodies to be more lenient with dopers. The lack of harmonization of sanctions has also frequently been the source of jurisdictional conflicts between

International Federations and National Anti-Doping Organizations.

The consensus of the World Conference on Doping in Sport held in Lausanne in February 1999 supported a two year period of Ineligibility for a first serious anti-doping rule violation followed with a lifetime ban for a second violation. This consensus was reflected in the OMADC.

10.3 Comment: This principle is carried over from the OMADC and allows, for example, some flexibility in disciplining Athletes who test positive as a result of the inadvertent use of a cold medicine containing a prohibited stimulant. "Reduction" of a sanction under Article 10.5.2 applies only to a second or third violation because the sanction for a first

substance was not intended to enhance sport performance, the period of *Ineligibility* found in Article 10.2 shall be replaced with the following:

- *First violation:* At a minimum, a warning and reprimand and no period of *Ineligibility* from future *Events*, and at a maximum, one (1) year's *Ineligibility*.
- *Second violation:* Two (2) years' *Ineligibility*.
- *Third violation:* Lifetime *Ineligibility*.

However, the *Athlete* or other *Person* shall have the opportunity in each case, before a period of *Ineligibility* is imposed, to establish the basis for eliminating or reducing (in the case of a second or third violation) this sanction as provided in Article 10.5.

10.4 *Ineligibility* for Other Anti-Doping Rule Violations

The period of *Ineligibility* for other anti-doping rule violations shall be:

10.4.1 For violations of Article 2.3 (refusing or failing to submit to *Sample* collection) or Article 2.5 (*Tampering with Doping Control*), the *Ineligibility* periods set forth in Article 10.2 shall apply.

10.4.2 For violations of Articles 2.7 (*Trafficking*) or 2.8 (administration of *Prohibited Substance* or *Prohibited Method*), the period of *Ineligibility* imposed shall be a minimum of four (4) years up to

violation already builds in sufficient discretion to allow consideration of the Person's degree of fault.

10.4.2 Comment: Those who are involved in doping *Athletes* or covering up doping should be subject to sanctions which are more severe than the *Athletes* who test positive.

Since the authority of sport organizations is generally limited to Ineligibility for credentials, membership and other sport benefits, reporting Athlete Support Personnel to competent authorities is an important step in the deterrence of doping.

lifetime *Ineligibility*. An anti-doping rule violation involving a *Minor* shall be considered a particularly serious violation, and, if committed by *Athlete Support Personnel* for violations other than specified substances referenced in Article 10.3, shall result in lifetime *Ineligibility* for such *Athlete Support Personnel*. In addition, violations of such Articles which also violate non-sporting laws and regulations, may be reported to the competent administrative, professional or judicial authorities.

10.4.3 For violations of Article 2.4 (whereabouts violation or missed test), the period of *Ineligibility* shall be at a minimum 3 months and at a maximum 2 years in accordance with the rules established by the *Anti-Doping Organization* whose test was missed or whereabouts requirement was violated. The period of *Ineligibility* for subsequent violations of Article 2.4 shall be as established in the rules of the *Anti-Doping Organization* whose test was missed or whereabouts requirement was violated.

10.5 Elimination or Reduction of Period of *Ineligibility* Based on Exceptional Circumstances.

10.5.1 *No Fault or Negligence*

If the *Athlete* establishes in an individual case involving an anti-doping rule violation under Article

10.4.3 Comment: The whereabouts and missed test policies of different *Anti-Doping Organizations* may vary considerably, particularly at the outset as these policies are being put into place. Thus, considerable flexibility has been provided for sanctioning these anti-doping rule violations. Those *Anti-Doping Organizations* with more sophisticated policies including built in safeguards, and those organizations with longer track

records of *Athlete* experience with a whereabouts policy, could provide for *Ineligibility* periods at the longer end of the specified range

10.5.1 Comment: Article 10.5.1 applies only to violations under Articles 2.1 and 2.2 (presence and Use of Prohibited Substances) because fault or negligence is already required to establish an anti-doping rule violation under other anti-doping rules.

2.1 (presence of *Prohibited Substance* or its *Metabolites* or *Markers*) or *Use of a Prohibited Substance* or *Prohibited Method* under Article 2.2 that he or she bears *No Fault or Negligence* for the violation, the otherwise applicable period of *Ineligibility* shall be eliminated. When a *Prohibited Substance* or its *Markers* or *Metabolites* is detected in an Athlete's Specimen in violation of Article 2.1 (presence of *Prohibited Substance*), the Athlete must also establish how the *Prohibited Substance* entered his or her system in order to have the period of *Ineligibility* eliminated. In the event this Article is applied and the period of *Ineligibility* otherwise applicable is eliminated, the anti-doping rule violation shall not be considered a violation for the limited purpose of determining the period of *Ineligibility* for multiple violations under Articles 10.2, 10.3 and 10.6.

10.5.2 No Significant Fault or Negligence

This Article 10.5.2 applies only to anti-doping rule violations involving Article 2.1 (presence of *Prohibited Substance* or its *Metabolites* or *Markers*), *Use of a Prohibited Substance* or

10.5.2 Comment: The trend in doping cases has been to recognize that there must be some opportunity in the course of the hearing process to consider the unique facts and circumstances of each particular case in imposing sanctions. This principle was accepted at the World Conference on Doping in Sport 1999 and was incorporated into the OMADC which provides that sanctions can be reduced in "exceptional circumstances." The Code also provides for the possible reduction or elimination of the period of *Ineligibility* in the unique circumstance where the Athlete can establish that he or she

had *No Fault or Negligence*, or *No Significant Fault or Negligence*, in connection with the violation. This approach is consistent with basic principles of human rights and provides a balance between those Anti-Doping Organizations that argue for a much narrower exception, or none at all, and those that would reduce a two year suspension based on a range of other factors even when the Athlete was admittedly at fault. These Articles apply only to the imposition of sanctions; they are not applicable to the determination of whether an anti-doping rule violation has occurred.

Prohibited Method under Article 2.2, failing to submit to *Sample* collection under Article 2.3, or administration of a *Prohibited Substance* or *Prohibited Method* under Article 2.8. If an Athlete establishes in an individual case involving such violations that he or she bears *No Significant Fault or Negligence*, then the period of *Ineligibility* may be reduced, but the reduced period of *Ineligibility* may not be less than one-half of the minimum period of *Ineligibility* otherwise applicable. If the otherwise applicable period of *Ineligibility* is a lifetime, the reduced period under this section may be no less than 8 years. When a *Prohibited Substance* or its *Markers* or *Metabolites* is detected in an Athlete's Specimen in violation of Article 2.1 (presence of *Prohibited Substance*), the Athlete must also establish how the *Prohibited Substance* entered his or her system in order to have the period of *Ineligibility* reduced.

Article 10.5 is meant to have an impact only in cases where the circumstances are truly exceptional and not in the vast majority of cases.

To illustrate the operation of Article 10.5, an example where *No Fault or Negligence* would result in the total elimination of a sanction is where an Athlete could prove that, despite all due care, he or she was sabotaged by a competitor. Conversely, a sanction could not be completely eliminated on the basis of *No Fault or Negligence* in the following circumstances: (a) a positive test resulting from a mislabeled or contaminated vitamin or nutritional supplement (Athletes are responsible for what they ingest (Article 2.1.1) and have been warned against the possibility of supplement contamination); (b) the administration of a prohibited substance by the Athlete's personal physician or

trainer without disclosure to the Athlete (Athletes are responsible for their choice of medical personnel and for advising medical personnel that they cannot be given any prohibited substance); and (c) sabotage of the Athlete's food or drink by a spouse, coach or other person within the Athlete's circle of associates (Athletes are responsible for what they ingest and for the conduct of those persons to whom they entrust access to their food and drink). However, depending on the unique facts of a particular case, any of the referenced illustrations could result in a reduced sanction based on *No Significant Fault or Negligence*. (For example, reduction may well be appropriate in illustration (a) if the Athlete clearly establishes that the cause of the positive test was contamination in a common multiple vitamin purchased from a source with no connection to

10.5.3 Athlete's Substantial Assistance in Discovering or Establishing Anti-Doping Rule Violations by Athlete Support Personnel and Others.

An *Anti-Doping Organization* may also reduce the period of *Ineligibility* in an individual case where the *Athlete* has provided substantial assistance to the *Anti-Doping Organization* which results in the *Anti-Doping Organization* discovering or establishing an anti-doping rule violation by another *Person* involving *Possession* under Article 2.6.2 (*Possession by Athlete Support Personnel*), Article 2.7 (*Trafficking*), or Article 2.8 (administration to an *Athlete*). The reduced period of *Ineligibility* may not, however, be less than one-half of the minimum period of *Ineligibility* otherwise applicable. If the otherwise applicable period of *Ineligibility* is a lifetime, the reduced period under this section may be no less than 8 years.

10.6 Rules for Certain Potential Multiple Violations

10.6.1 For purposes of imposing sanctions under Articles 10.2, 10.3 and 10.4, a second anti-doping rule violation may be considered for purposes of imposing sanctions only if the *Anti-Doping*

Prohibited Substances and the Athlete exercised care in not taking other nutritional supplements.)

Article 10.5.2 applies only to the identified anti-doping rule violations because these violations may be based on conduct that is not intentional or purposeful. Violations under Article 2.4 (whereabouts information and missed tests) are not included, even though intentional conduct is not required to establish these violations because the sanction for violations of Article 2.4

(from three months to two years) already builds in sufficient discretion to allow consideration of the *Athlete's* degree of fault.

10.6.1 Comment: Under this Article, an *Athlete* testing positive a second time before notice of the first positive test would only be sanctioned on the basis of a single anti-doping rule violation.

Organization can establish that the *Athlete* or other *Person* committed the second anti-doping rule violation after the *Athlete* or other *Person* received notice, or after the *Anti-Doping Organization* made a reasonable *Attempt* to give notice, of the first anti-doping rule violation; if the *Anti-Doping Organization* cannot establish this, the violations shall be considered as one single first violation, and the sanction imposed shall be based on the violation that carries the more severe sanction.

10.6.2 Where an *Athlete*, based on the same *Doping Control*, is found to have committed an anti-doping rule violation involving both a specified substance under Article 10.3 and another *Prohibited Substance* or *Prohibited Method*, the *Athlete* shall be considered to have committed a single anti-doping rule violation, but the sanction imposed shall be based on the *Prohibited Substance* or *Prohibited Method* that carries the most severe sanction.

10.6.3 Where an *Athlete* is found to have committed two separate anti-doping rule violations, one involving a specified substance governed by the sanctions set forth in Article 10.3 (Specified Substances) and the

10.6.3 Comment: Article 10.6.3 deals with the situation where an *Athlete* commits two separate anti-doping rule violations, but one of the violations involves a specified substance governed by the lesser sanctions of Article 10.3. Without this Article in the Code, the second offense arguably could be governed by the sanction applicable to a second violation for the *Prohibited Substance* involved in the second violation, the sanction applicable to a second offense for the substance involved in the first violation, or a combination of the sanctions applicable to the two

offenses. This Article imposes a combined sanction calculated by adding together the sanctions for a first offense under 10.2 (two years) and a first offense under 10.3 (up to one year). This provides the same sanction to the *Athlete* that commits a first violation under 10.2 followed by a second violation involving a specified substance, and the *Athlete* that commits a first violation involving a specified substance followed by a second violation under 10.2. In both cases, the sanction shall be from two years to three years' *Ineligibility*.

other involving a *Prohibited Substance* or *Prohibited Method* governed by the sanctions set forth in Article 10.2 or a violation governed by the sanctions in Article 10.4.1, the period of *Ineligibility* imposed for the second offense shall be at a minimum two years' *Ineligibility* and at a maximum three years' *Ineligibility*. Any *Athlete* found to have committed a third anti-doping rule violation involving any combination of specified substances under Article 10.3 and any other anti-doping rule violation under 10.2 or 10.4.1 shall receive a sanction of lifetime *Ineligibility*.

10.7 Disqualification of Results in Competitions Subsequent to Sample Collection

In addition to the automatic *Disqualification* of the results in the *Competition* which produced the positive *Sample* under Article 9 (Automatic *Disqualification* of Individual Results), all other competitive results obtained from the date a positive *Sample* was collected (whether *In-Competition* or *Out-of-Competition*), or other doping violation occurred, through the commencement of any *Provisional Suspension* or *Ineligibility* period, shall, unless fairness requires otherwise, be *Disqualified* with all of the resulting consequences including forfeiture of any medals, points and prizes.

10.8 Commencement of Ineligibility Period

The period of *Ineligibility* shall start on the date of the hearing decision providing for *Ineligibility* or, if the hearing is waived, on the date *Ineligibility* is accepted or otherwise imposed. Any period of *Provisional Suspension* (whether imposed or voluntarily accepted) shall be credited against

10.8 Comment: Currently, many Anti-Doping Organizations start the two-year period of *Ineligibility* at the time a hearing decision is rendered. Those Anti-Doping Organizations also

frequently invalidate results retroactively to the date a positive *Sample* was collected. Other Anti-Doping Organizations simply start the two-year suspension on the date the

the total period of *Ineligibility* to be served. Where required by fairness, such as delays in the hearing process or other aspects of *Doping Control* not attributable to the *Athlete*, the body imposing the sanction may start the period of *Ineligibility* at an earlier date commencing as early as the date of *Sample* collection.

10.9 Status During Ineligibility

No *Person* who has been declared *Ineligible* may, during the period of *Ineligibility*, participate in any capacity in a *Competition* or activity (other than authorized anti-doping education or rehabilitation programs) authorized or organized by any *Signatory* or *Signatory's* member organization. In addition, for any anti-doping rule violation not involving specified substances described in Article 10.3, some or all sport-related financial support or other sport-related benefits received by such *Person* will be withheld by *Signatories*. *Signatories'* member organizations and governments. A *Person* subject to a period of *Ineligibility* longer than four years may, after completing four years of the period of *Ineligibility*,

positive *Sample* was collected. The OMADC, as clarified by its Explanatory Document, does not mandate either approach. The approach provided in the Code gives *Athletes* a strong disincentive to drag out the hearing process while they compete in the interim. It also encourages them to voluntarily accept *Provisional Suspensions* pending a hearing. On the other hand, the body imposing the sanction can start the sanction running before the date the hearing decision is reached so that an *Athlete* is not penalized by delays in the *Doping Control* process which are not his or her fault, for example, inordinate delay by the laboratory in reporting a positive test or delays in scheduling the hearing caused by the Anti-Doping Organization.

10.9 Comment: The rules of some Anti-Doping Organizations only ban an *Athlete* from "competing" during a period of *Ineligibility*. For example, an *Athlete* in those sports could still coach during the *Ineligibility* period. This Article adopts the position set forth in the OMADC that an *Athlete* who is made ineligible for doping should not participate in any capacity in an authorized Event or activity during the *Ineligibility* period. This would preclude, for example, practicing with a national team, or acting as a coach or sport official. Sanctions in one sport will also be recognized by other sports (see Article 15.4). This article would not prohibit the *Person* from participating in sport on a purely recreational level.

participate in local sport events in a sport other than the sport in which the *Person* committed the anti-doping rule violation, but only so long as the local sport event is not at a level that could otherwise qualify such *Person* directly or indirectly to compete in (or accumulate points toward) a national championship or *International Event*.

10.10 Reinstatement Testing

As a condition to regaining eligibility at the end of a specified period of *Ineligibility*, an *Athlete* must, during any period of *Provisional Suspension* or *Ineligibility*, make him or herself available for *Out-of-Competition Testing* by any *Anti-Doping Organization* having testing jurisdiction, and must, if requested, provide current and accurate whereabouts information. If an *Athlete* subject to a period of *Ineligibility* retires from sport and is removed from *Out-of-Competition Testing* pools and later seeks reinstatement, the *Athlete* shall not be eligible for reinstatement until the *Athlete* has notified relevant *Anti-Doping Organizations* and has been subject to *Out-of-Competition Testing* for a period of time equal to the period of *Ineligibility* remaining as of the date the *Athlete* had retired.

ARTICLE 11 CONSEQUENCES TO TEAMS

Where more than one team member in a *Team Sport* has been notified of a possible anti-doping rule violation under Article 7 in connection with an *Event*, the Team shall be subject to *Target Testing* for the *Event*. If more than one team member in a *Team Sport* is found to have committed an anti-doping rule violation during the *Event*, the team may be subject to *Disqualification* or other disciplinary action. In sports which are not *Team Sports* but

10.10 Comment: On a related issue, the Code does not establish a rule, but rather leaves it to the various Anti-Doping Organizations to establish their own rules addressing eligibility

requirements for Athletes who are not ineligible and retire from sport while included in an Out-of-Competition pool and then seek to return to active participation in sport.

where awards are given to teams, *Disqualification* or other disciplinary action against the team when one or more team members have committed an anti-doping rule violation shall be as provided in the applicable rules of the International Federation.

ARTICLE 12 SANCTIONS AGAINST SPORTING BODIES

Nothing in this *Code* precludes any *Signatory* or government accepting the *Code* from enforcing its own rules for the purpose of imposing sanctions on another sporting body over which the *Signatory* or government has authority.

ARTICLE 13 APPEALS

13.1 Decisions Subject to Appeal

Decisions made under the *Code* or rules adopted pursuant to the *Code* may be appealed as set forth below in Articles 13.2 through 13.4. Such decisions shall remain in effect while under appeal unless the appellate body orders otherwise. Before an appeal is commenced, any post-decision review provided in the *Anti-Doping Organization's* rules must be exhausted, provided that such review respects the principles set forth in Article 13.2.2 below.

13.2 Appeals from Decisions Regarding Anti-Doping Rule Violations, Consequences, and Provisional Suspensions

A decision that an anti-doping rule violation was committed, a decision imposing *Consequences* for an anti-doping rule violation, a decision that no anti-doping rule violation was committed, a decision that an *Anti-Doping Organization* lacks jurisdiction to rule on an alleged anti-doping rule violation or its *Consequences*.

12 Comment: This Article makes it clear that the Code does not restrict whatever disciplinary rights between organizations may otherwise exist.

13.1 Comment: The comparable OMADC Article is broader in that it provides that any dispute arising out of the application of the OMADC may be appealed to CAS.

and a decision to impose a *Provisional Suspension* as a result of a *Provisional Hearing* or in violation of Article 7.5 may be appealed exclusively as provided in this Article 13.2.

13.2.1 Appeals Involving *International-Level Athletes*

In cases arising from competition in an *International Event* or in cases involving *International-Level Athletes*, the decision may be appealed exclusively to the Court of Arbitration for Sport ("CAS") in accordance with the provisions applicable before such court.

13.2.2 Appeals Involving *National-Level Athletes*

In cases involving national-level *Athletes*, as defined by each *National Anti-Doping Organization*, that do not have a right to appeal under Article 13.2.1, the decision may be appealed to an independent and impartial body in accordance with rules established by the *National Anti-Doping Organization*. The rules for such appeal shall respect the following principles:

- A timely hearing;
- Fair, impartial and independent hearing body;
- The right to be represented by counsel at the *Person's* own expense; and
- A timely, written, reasoned decision.

13.2.3 *Persons* Entitled to Appeal

In cases under Article 13.2.1, the following parties shall have the right to appeal to CAS: (a) the *Athlete*

13.2.1 Comment: CAS decisions are final and binding except for any review required by law applicable to the annulment or enforcement of arbitral awards.

13.2.2 Comment: An *Anti-Doping Organization* may elect to comply with this Article by giving its national-level *Athletes* the right to appeal directly to CAS.

or other *Person* who is the subject of the decision being appealed; (b) the other party to the case in which the decision was rendered; (c) the relevant International Federation and any other *Anti-Doping Organization* under whose rules a sanction could have been imposed; (d) the International Olympic Committee or International Paralympic Committee, as applicable, where the decision may have an effect in relation to the Olympic Games or Paralympic Games, including decisions affecting eligibility for the Olympic Games or Paralympic Games; and (e) WADA. In cases under Article 13.2.2, the parties having the right to appeal to the national-level reviewing body shall be as provided in the *National Anti-Doping Organization's* rules but, at a minimum, shall include: (a) the *Athlete* or other *Person* who is the subject of the decision being appealed; (b) the other party to the case in which the decision was rendered; (c) the relevant International Federation; and (d) WADA. For cases under Article 13.2.2, WADA and the International Federation shall also have the right to appeal to CAS with respect to the decision of the national-level reviewing body.

Notwithstanding any other provision herein, the only *Person* that may appeal from a *Provisional Suspension* is the *Athlete* or other *Person* upon whom the *Provisional Suspension* is imposed.

13.3 Appeals from Decisions Granting or Denying a Therapeutic Use Exemption

Decisions by WADA reversing the grant or denial of a therapeutic use exemption may be appealed exclusively to CAS by the *Athlete* or the *Anti-Doping Organization* whose decision was reversed. Decisions by *Anti-Doping Organizations* other than WADA denying therapeutic use exemptions, which are not reversed by WADA, may be appealed by *International-Level Athletes* to CAS and by

other *Athletes* to the national level reviewing body described in Article 13.2.2. If the national level reviewing body reverses the decision to deny a therapeutic use exemption, that decision may be appealed to CAS by WADA.

13.4 Appeals from Decisions Imposing *Consequences* under Part Three of the *Code*

With respect to *consequences* imposed under Part Three (Roles and Responsibilities) of the *Code*, the entity upon which *consequences* are imposed under Part Three of the *Code* shall have the right to appeal exclusively to CAS in accordance with the provisions applicable before such court.

13.5 Appeals from Decisions Suspending or Revoking Laboratory Accreditation

Decisions by WADA to suspend or revoke a laboratory's WADA accreditation may be appealed only by that laboratory with the appeal being exclusively to CAS.

ARTICLE 14 CONFIDENTIALITY AND REPORTING

The *Signatories* agree to the principles of coordination of anti-doping results, public transparency and accountability and respect for the privacy interests of individuals alleged to have violated anti-doping rules as provided below:

14.1 Information Concerning *Adverse Analytical Findings* and Other Potential Anti-Doping Rule Violations

An *Athlete* whose *Sample* has resulted in an *Adverse Analytical Finding*, or an *Athlete* or other *Person* who may

13.5 Comment: The object of the *Code* is to have anti-doping matters resolved through fair and transparent internal processes with a final appeal. Anti-doping decisions by Anti-Doping Organizations are made transparent in Article 14. Specified Persons and organizations, including WADA, are

then given the opportunity to appeal those decisions. Note, that the definition of interested Persons and organizations with a right to appeal under Article 13 does not include Athletes, or their federations, who might benefit from having another competitor disqualified.

have violated an anti-doping rule, shall be notified by the *Anti-Doping Organization* with results management responsibility as provided in Article 7 (Results Management). The *Athlete's National Anti-Doping Organization* and International Federation and WADA shall also be notified not later than the completion of the process described in Articles 7.1 and 7.2. Notification shall include: the *Athlete's* name, country, sport and discipline within the sport, whether the test was *In-Competition* or *Out-of-Competition*, the date of *Sample* collection and the analytical result reported by the laboratory. The same *Persons* and *Anti-Doping Organizations* shall be regularly updated on the status and findings of any review or proceedings conducted pursuant to Articles 7 (Results Management), 8 (Right to a Fair Hearing) or 13 (Appeals), and, in any case in which the period of *Ineligibility* is eliminated under Article 10.5.1 (*No Fault or Negligence*), or reduced under Article 10.5.2 (*No Significant Fault or Negligence*), shall be provided with a written reasoned decision explaining the basis for the elimination or reduction. The recipient organizations shall not disclose this information beyond those persons within the organization with a need to know until the *Anti-Doping Organization* with results management responsibility has made public disclosure or has failed to make public disclosure as required in Article 14.2 below.

14.2 Public Disclosure

The identity of *Athletes* whose *Samples* have resulted in *Adverse Analytical Findings*, or *Athletes* or other *Persons* who were alleged by an *Anti-Doping Organization* to have violated other anti-doping rules, may be publicly disclosed by the *Anti-doping Organization* with results management responsibility no earlier than completion of the administrative review described in Articles 7.1 and 7.2. No later than twenty days after it has been determined in a hearing in accordance with Article 8 that an anti-doping rule violation has occurred, or such hearing has been

waived, or the assertion of an anti-doping rule violation has not been timely challenged, the *Anti-Doping Organization* responsible for results management must publicly report the disposition of the anti-doping matter.

14.3 Athlete Whereabouts Information

Athletes who have been identified by their International Federation or *National Anti-Doping Organization* for inclusion in an *Out-of-Competition Testing* pool shall provide accurate, current location information. The International Federations and *National Anti-Doping Organizations* shall coordinate the identification of *Athletes* and the collecting of current location information and shall submit it to WADA. WADA shall make this information accessible to other *Anti-Doping Organizations* having authority to test the *Athlete* as provided in Article 15. This information shall be maintained in strict confidence at all times; shall be used exclusively for purposes of planning, coordinating or conducting *Testing*; and shall be destroyed after it is no longer relevant for these purposes.

14.4 Statistical Reporting

Anti-Doping Organizations shall, at least annually, publish publicly a general statistical report of their *Doping Control* activities with a copy provided to WADA.

14.5 Doping Control Information Clearing House

WADA shall act as a central clearing house for *Doping Control Testing* data and results for *International-Level Athletes* and national-level *Athletes* that have been included in their *National Anti-Doping Organization's Registered Testing Pool*. To facilitate coordinated test distribution planning and to avoid unnecessary duplication in *Testing* by the various *Anti-Doping Organizations*, each *Anti-Doping Organization* shall report all *In-Competition* and *Out-of-Competition* tests on such *Athletes* to the WADA clearinghouse as soon as possible after such tests have been conducted. WADA shall make this information accessible to the *Athlete*, the *Athlete's National Federation*, *National Olympic Committee* or *National*

Paralympic Committee, *National Anti-Doping Organization*, *International Federation*, and the *International Olympic Committee* or *International Paralympic Committee*. Private information regarding an *Athlete* shall be maintained by WADA in strict confidence. WADA shall, at least annually, publish statistical reports summarizing such information.

ARTICLE 15: CLARIFICATION OF DOPING CONTROL RESPONSIBILITIES

15.1 Event Testing

The collection of *Samples for Doping Control* does and should take place at both *International Events* and *National Events*. However, only a single organization should be responsible for initiating and directing *Testing* during an *Event*. At *International Events*, the collection of *Doping Control Samples* shall be initiated and directed by the international organization which is the ruling body for the *Event* (e.g., the IOC for the Olympic Games, the International Federation for a World Championship, and PASO for the Pan American Games). If the international organization decides not to conduct any *Testing* at such an *Event*, the *National Anti-Doping Organization* for the country where the *Event* occurs may, in coordination with and with the approval of the international organization or WADA, initiate and conduct such *Testing*. At *National Events*, the collection of *Doping Control Samples* shall be initiated and directed by the designated *National Anti-Doping Organization* of that country.

15 Comment: To be effective, the anti-doping effort must involve many *Anti-Doping Organizations* conducting strong programs at both the international and national levels. Rather than limiting the responsibilities of one group in favor of the exclusive competency of the other, the Code manages potential problems associated with overlapping responsibilities, first by creating a much higher level of overall harmonization

and second, by establishing rules of precedence and cooperation in specific areas.

15.1 Comment: The *Anti-Doping Organization* "initiating and directing testing" may, if it chooses, enter into agreements with other organizations to which it delegates responsibility for Sample collection or other aspects of the *Doping Control* process.

15.2 Out-of-Competition Testing

Out-of-Competition Testing is and should be initiated and directed by both international and national organizations. *Out-of-Competition Testing* may be initiated and directed by: (a) WADA; (b) the IOC or IPC in connection with the Olympic Games or Paralympic Games; (c) the *Athlete's* International Federation; (d) the *Athlete's National Anti-Doping Organization*; or (e) the *National Anti-Doping Organization* of any country where the *Athlete* is present. *Out-of-Competition Testing* should be coordinated through WADA in order to maximize the effectiveness of the combined *Testing* effort and to avoid unnecessary repetitive *Testing* of individual *Athletes*.

15.3 Results Management, Hearings and Sanctions

Except as provided in Article 15.3.1 below, results management and hearings shall be the responsibility of and shall be governed by the procedural rules of the *Anti-Doping Organization* that initiated and directed *Sample* collection (or, if no *Sample* collection is involved, the organization which discovered the violation). Regardless of which organization conducts results management or hearings, the principles set forth in Articles 7 and 8 shall be respected and the rules identified in the Introduction to Part One to be incorporated without substantive change must be followed.

15.3.1 Results management and the conduct of hearings for an anti-doping rule violation arising from a test by, or discovered by, a *National Anti-Doping Organization* involving an *Athlete* that is not a citizen

15.2 Comment: Additional authority to conduct *Testing* may be authorized by means of bilateral or multilateral agreements among Signatories and governments.

15.3 Comment: In some cases, the procedural rules of the *Anti-Doping Organization* which initiated and directed the *Sample* collection may

specify that results management will be handled by another organization (e.g., the *Athlete's* national federation). In such event, it shall be the *Anti-Doping Organization's* responsibility to confirm that the other organization's rules are consistent with the Code.

15.3.1 Comment: No absolute rule is established for managing results and

or resident of that country shall be administered as directed by the rules of the applicable International Federation. Results management and the conduct of hearings from a test by the International Olympic Committee, the International Paralympic Committee, or a *Major Event Organization*, shall be referred to the applicable International Federation as far as sanctions beyond *Disqualification* from the *Event* or the results of the *Event*.

15.4 Mutual Recognition

Subject to the right to appeal provided in Article 13, the *Testing*, therapeutic use exemptions and hearing results or other final adjudications of any *Signatory* which are consistent with the *Code* and are within that *Signatory's* authority, shall be recognized and respected by all other *Signatories*. *Signatories* may recognize the same actions of other bodies which have not accepted the *Code* if the rules of those bodies are otherwise consistent with the *Code*.

ARTICLE 16: DOPING CONTROL FOR ANIMALS COMPETING IN SPORT

16.1 In any sport that includes animals in competition, the International Federation for that sport shall establish and implement anti-doping rules for the animals included in that sport. The anti-doping rules shall include a list of *Prohibited Substances*, appropriate *Testing* procedures and a list of approved laboratories for *Sample* analysis.

conducting hearings where a *National Anti-Doping Organization* tests a foreign national athlete over whom it would have had no jurisdiction but for the *Athlete's* presence in the *National Anti-Doping Organization's* country. Under this Article, it is left to the International Federation to determine under its own rules whether, for example, management of the case

should be referred to the *Athlete's* *National Anti-Doping Organization*, remain with the *Anti-Doping Organization* that collected the *Sample*, or be taken over by the International Federation.

- 16.2** With respect to determining anti-doping rule violations, results management, fair hearings, *Consequences*, and appeals for animals involved in sport, the International Federation for that sport shall establish and implement rules that are generally consistent with Articles 1, 2, 3, 9, 10, 11, 13 and 17 of the *Code*.

ARTICLE 17: STATUTE OF LIMITATIONS

No action may be commenced against an *Athlete* or other *Person* for a violation of an anti-doping rule contained in the *Code* unless such action is commenced within eight years from the date the violation occurred.

17 Comment: *This does not restrict the Anti-Doping Organization from considering an earlier anti-doping violation for purposes of the sanction for a subsequent violation that occurs more than eight years later. In other words, a second violation ten years after a first violation is considered a second violation for sanction purposes.*

PART TWO

EDUCATION & RESEARCH

ARTICLE 18: EDUCATION**18.1 Basic Principle and Primary Goal**

The basic principle for information and education programs shall be to preserve the spirit of sport as described in the Introduction to the *Code*, from being undermined by doping. The primary goal shall be to dissuade *Athletes* from using *Prohibited Substances* and *Prohibited Methods*.

18.2 Program and Activities

Each *Anti-Doping Organization* should plan, implement and monitor information and education programs. The programs should provide *Participants* with updated and accurate information on at least the following issues:

- Substances and methods on the *Prohibited List*
- Health consequences of doping
- *Doping Control* procedures
- *Athletes'* rights and responsibilities

The programs should promote the spirit of sport in order to establish an anti-doping environment which influences behavior among *Participants*.

Athlete Support Personnel should educate and counsel *Athletes* regarding anti-doping policies and rules adopted pursuant to the *Code*.

18.3 Coordination and Cooperation

All *Signatories* and *Participants* shall cooperate with each other and governments to coordinate their efforts in anti-doping information and education.

ARTICLE 19: RESEARCH**19.1 Purpose of Anti-Doping Research**

Anti-doping research contributes to the development and implementation of efficient programs within *Doping Control* and to anti-doping information and education.

19.2 Types of Research

Anti-doping research may include, for example, sociological, behavioral, juridical and ethical studies in addition to medical, analytical and physiological investigation.

19.3 Coordination

Coordination of anti-doping research through WADA is encouraged. Subject to intellectual property rights, copies of anti-doping research results should be provided to WADA.

19.4 Research Practices

Anti-doping research shall comply with internationally recognized ethical practices.

19.5 Research Using *Prohibited Substances* and *Prohibited Methods*

Research efforts should avoid the administration of *Prohibited Substances* or *Prohibited Methods* to *Athletes*.

19.6 Misuse of Results

Adequate precautions should be taken so that the results of anti-doping research are not misused and applied for doping.

PART THREE

ROLES & RESPONSIBILITIES

ARTICLE 20: ADDITIONAL ROLES AND RESPONSIBILITIES OF SIGNATORIES

20.1 Roles and Responsibilities of the International Olympic Committee

20.1.1 To adopt and implement anti-doping policies and rules for the Olympic Games which conform with the *Code*.

20.1.2 To require as a condition of recognition by the International Olympic Committee, that International Federations within the Olympic Movement are in compliance with the *Code*.

20.1.3 To withhold some or all Olympic funding of sport organizations that are not in compliance with the *Code*.

20.1.4 To take appropriate action to discourage non-compliance with the *Code* as provided in Article 23.5.

20.1.5 To authorize and facilitate the *Independent Observer Program*.

20.2 Roles and Responsibilities of the International Paralympic Committee

20.2.1 To adopt and implement anti-doping policies and rules for the Paralympic Games which conform with the *Code*.

20.2.2 To require as a condition of recognition by the International Paralympic Committee, that National Paralympic Committees within the Olympic Movement are in compliance with the *Code*.

20 Comment: Responsibilities for Signatories and Participants are addressed in various articles in the

Code and the responsibilities listed in this part are additional to these responsibilities.

20.2.3 To withhold some or all Paralympic funding of sport organizations that are not in compliance with the *Code*.

20.2.4 To take appropriate action to discourage non-compliance with the *Code* as provided in Article 23.5.

20.2.5 To authorize and facilitate the *Independent Observer Program*.

20.3 Roles and Responsibilities of International Federations

20.3.1 To adopt and implement anti-doping policies and rules which conform with the *Code*.

20.3.2 To require as a condition of membership that the policies, rules and programs of National Federations are in compliance with the *Code*.

20.3.3 To require all *Athletes* and *Athlete Support Personnel* within their jurisdiction to recognize and be bound by anti-doping rules in conformance with the *Code*.

20.3.4 To require *Athletes* who are not regularly members of the International Federation or one of its member National Federations to be available for *Sample* collection and provide accurate and up-to-date whereabouts information if required by the conditions for eligibility established by the International Federation or, as applicable, the *Major Event Organization*.

20.3.5 To monitor the anti-doping programs of National Federations.

20.3.4 Comment: This would include, for example, *Athletes* from professional leagues.

- 20.3.6** To take appropriate action to discourage non-compliance with the *Code* as provided in Article 23.5.
- 20.3.7** To authorize and facilitate the *Independent Observer* program at *International Events*.
- 20.3.8** To withhold some or all funding to its member National Federations that are not in compliance with the *Code*.
- 20.4** Roles and Responsibilities of *National Olympic Committees* and *National Paralympic Committees*
- 20.4.1** To ensure that their anti-doping policies and rules conform with the *Code*.
- 20.4.2** To require as a condition of membership or recognition that National Federations' anti-doping policies and rules are in compliance with the applicable provisions of the *Code*.
- 20.4.3** To require *Athletes* who are not regular members of a National Federation to be available for *Sample* collection and provide accurate and up-to-date whereabouts information on a regular basis if required during the year before the Olympic Games as a condition of participation in the Olympic Games.
- 20.4.4** To cooperate with their *National Anti-Doping Organization*.
- 20.4.5** To withhold some or all funding, during any period of his or her *Ineligibility*, to any *Athlete* or *Athlete Support Personnel* who has violated anti-doping rules.
- 20.4.6** To withhold some or all funding to its member or recognized National Federations that are not in compliance with the *Code*.

- 20.5** Roles and Responsibilities of *National Anti-Doping Organizations*
- 20.5.1** To adopt and implement anti-doping rules and policies which conform with the *Code*.
- 20.5.2** To cooperate with other relevant national organizations and other *Anti-Doping Organizations*.
- 20.5.3** To encourage reciprocal testing between *National Anti-Doping Organizations*.
- 20.5.4** To promote anti-doping research.
- 20.6** Roles and Responsibilities of *Major Event Organizations*
- 20.6.1** To adopt and implement anti-doping policies and rules for their *Events* which conform with the *Code*.
- 20.6.2** To take appropriate action to discourage non-compliance with the *Code* as provided in Article 23.5.
- 20.6.3** To authorize and facilitate the *Independent Observer Program*.
- 20.7** Roles and Responsibilities of *WADA*
- 20.7.1** To adopt and implement policies and procedures which conform with the *Code*.
- 20.7.2** To monitor the processing of *Adverse Analytical Findings*.
- 20.7.3** To approve *International Standards* applicable to the implementation of the *Code*.
- 20.7.4** To accredit laboratories to conduct *Sample* analysis or to approve others to conduct *Sample* analysis.

- 20.7.5 To develop and approve Models of Best Practice.
- 20.7.6 To promote, conduct, commission, fund and coordinate anti-doping research.
- 20.7.7 To conduct an effective *Independent Observer Program*.
- 20.7.8 To conduct *Doping Controls* as authorized by other *Anti-Doping Organizations*.

ARTICLE 21: ROLES AND RESPONSIBILITIES OF PARTICIPANTS

21.1 Roles and Responsibilities of *Athletes*

- 21.1.1 To be knowledgeable of and comply with all applicable anti-doping policies and rules adopted pursuant to the *Code*.
- 21.1.2 To be available for *Sample* collection.
- 21.1.3 To take responsibility, in the context of anti-doping, for what they ingest and use.
- 21.1.4 To inform medical personnel of their obligation not to *Use Prohibited Substances* and *Prohibited Methods* and to take responsibility to make sure that any medical treatment received does not violate anti-doping policies and rules adopted pursuant to the *Code*.

21.2 Roles and Responsibilities of *Athlete Support Personnel*

- 21.2.1 To be knowledgeable of and comply with all anti-doping policies and rules adopted pursuant to the *Code* and which are applicable to them or the *Athletes* whom they support.
- 21.2.2 To cooperate with the *Athlete Testing* program.

- 21.2.3 To use their influence on *Athlete* values and behavior to foster anti-doping attitudes.

ARTICLE 22: INVOLVEMENT OF GOVERNMENTS

Each government's commitment to the *Code* will be evidenced by its signing a Declaration on or before the first day of the Athens Olympic Games to be followed by a process leading to a convention or other obligation to be implemented as appropriate to the constitutional and administrative contexts of each government on or before the first day of the Turin Winter Olympic Games.

It is the expectation of the *Signatories* that the Declaration and the convention or other obligation will reflect the following major points:

- 22.1 Affirmative measures will be undertaken by each government in support of anti-doping in at least the following areas:
 - Support for national anti-doping programs;
 - The availability of *Prohibited Substances* and *Prohibited Methods*;
 - Facilitate access for WADA to conduct *Out-of-Competition Doping Controls*;
 - The problem of nutritional supplements which contain undisclosed *Prohibited Substances*; and
 - Withholding some or all financial support from sport organizations and *Participants* that are not in compliance with the *Code* or applicable anti-doping rules adopted pursuant to the *Code*.

22 Comment: Most governments cannot be parties to, or be bound by, private non-governmental instruments such as the *Code*. For that reason, governments are not asked to be *Signatories* to the *Code*. However, the effort to combat doping through the coordinated and harmonized program reflected in the *Code* is very much a

joint effort between the sport movement and governments. An example of one type of obligation referred to above is the convention discussed in the Final Communiqué of the UNESCO Round Table of Ministers and Senior Officials Responsible for Physical Education and Sport held in Paris on 9/10 January 2003.

- 22.2** All other governmental involvement with anti-doping will be brought into harmony with the *Code*.
- 22.3** Ongoing compliance with the commitments reflected in the convention or other obligation will be monitored as determined in consultation between *WADA* and the applicable government(s).

PART FOUR

ACCEPTANCE, COMPLIANCE, MODIFICATION & INTERPRETATION

ARTICLE 23: ACCEPTANCE, COMPLIANCE AND MODIFICATION**23.1 Acceptance of the Code**

23.1.1 The following entities shall be *Signatories* accepting the Code: WADA, The International Olympic Committee, International Federations, The International Paralympic Committee, *National Olympic Committees*, National Paralympic Committees, *Major Event Organizations*, and *National Anti-Doping Organizations*. These entities shall accept the Code by signing a declaration of acceptance upon approval by each of their respective governing bodies.

23.1.2 Other sport organizations that may not be under the control of a *Signatory* may, upon WADA's invitation, also accept the Code.

23.1.3 A list of all acceptances will be made public by WADA.

23.2 Implementation of the Code

23.2.1 The *Signatories* shall implement applicable Code provisions through policies, statutes, rules or regulations according to their authority and within their relevant spheres of responsibility.

23.1.1 Comment: Each accepting Signatory will separately sign an identical copy of the standard form common declaration of acceptance and deliver it to WADA. The act of acceptance will be as authorized by the organic documents of each organization. For example, an International Federation by its Congress and WADA by its Foundation Board.

23.1.2 Comment: Those professional leagues that are not currently under the jurisdiction of any government or International Federation will be encouraged to accept the Code.

23.2.2 In implementing the Code, the *Signatories* are encouraged to use the Models of Best Practice recommended by WADA.

23.3 Acceptance and Implementation Deadlines

23.3.1 *Signatories* shall accept and implement the Code on or before the first day of the Athens Olympic Games.

23.3.2 The Code may be accepted after the above-referenced deadlines; however, *Signatories* shall not be considered in compliance with the Code until they have accepted the Code (and that acceptance has not been withdrawn).

23.4 Monitoring Compliance with the Code

23.4.1 Compliance with the Code shall be monitored by WADA or as otherwise agreed by WADA.

23.4.2 To facilitate monitoring, each *Signatory* shall report to WADA on its compliance with the Code every second year and shall explain reasons for noncompliance.

23.4.3 WADA shall consider explanations for non-compliance and, in extraordinary situations, may recommend to the International Olympic Committee, International Paralympic Committee, International Federations, and *Major Event Organizations* that they provisionally excuse the non-compliance.

23.4.3 Comment: WADA recognizes that amongst Signatories and governments, there will be significant differences in anti-doping experience, resources, and the legal context in

which anti-doping activities are carried out. In considering whether an organization is compliant, WADA will consider these differences.

23.4.4 WADA shall, after dialogue with the subject organization, make reports on compliance to the International Olympic Committee, the International Paralympic Committee, International Federations, and *Major Event Organizations*. These reports shall also be made available to the public.

23.5 Consequences of Noncompliance with the *Code*

23.5.1 Noncompliance with the *Code* by either the government or *National Olympic Committee* of a country may result in consequences with respect to Olympic Games, Paralympic Games, World Championships or the *Events of Major Event Organizations* as determined by the ruling body for each *Event*. The imposition of such consequences may be appealed by the *National Olympic Committee* or government to CAS pursuant to Article 13.4.

23.6 Modification of the *Code*

23.6.1 WADA shall be responsible for overseeing the evolution and improvement of the *Code*. *Athletes* and all *Signatories* and governments shall be invited to participate in such process.

23.6.2 WADA shall initiate proposed amendments to the *Code* and shall ensure a consultative process to both receive and respond to recommendations and to facilitate review and feedback from *Athletes*, *Signatories* and governments on recommended amendments.

23.6.3 Amendments to the *Code* shall, after appropriate consultation, be approved by a two-thirds majority of the WADA Foundation Board including a majority of both the public sector and Olympic Movement members casting votes. Amendments shall, unless provided otherwise, go into effect three months after such approval.

23.6.4 *Signatories* shall implement any applicable amendment to the *Code* within one year of approval by the WADA Foundation Board.

23.7 Withdrawal of Acceptance of the *Code*

23.7.1 *Signatories* may withdraw acceptance of the *Code* after providing WADA six-month's written notice of their intent to withdraw.

ARTICLE 24: INTERPRETATION OF THE CODE

24.1 The official text of the *Code* shall be maintained by WADA and shall be published in English and French. In the event of any conflict between the English and French versions, the English version shall prevail.

24.2 The comments annotating various provisions of the *Code* are included to assist in the understanding and interpretation of the *Code*.

24.3 The *Code* shall be interpreted as an independent and autonomous text and not by reference to the existing law or statutes of the *Signatories* or governments.

- 24.4** The headings used for the various Parts and Articles of the *Code* are for convenience only and shall not be deemed part of the substance of the *Code* or to affect in any way the language of the provisions to which they refer.
- 24.5** The *Code* shall not apply retrospectively to matters pending before the date the *Code* is accepted by a Signatory and implemented in its rules.
- 24.6** APPENDIX I Definitions shall be considered an integral part of the *Code*.

24.5 Comment: For example, conduct which is an anti-doping rule violation described in the Code, but which is not a violation under an International Federation's pre-Code rules, would not be a violation until the International Federation's rules are changed.

Pre-Code anti-doping rule violations would continue to count as "First violations" or "Second violations" for purposes of determining sanctions under Article 10 for subsequent post-Code violations.

APPENDIX 1

DEFINITIONS

Adverse Analytical Finding: A report from a laboratory or other approved *Testing* entity that identifies in a *Specimen* the presence of a *Prohibited Substance* or its *Metabolites* or *Markers* (including elevated quantities of endogenous substances) or evidence of the *Use of a Prohibited Method*.

Anti-Doping Organization: A *Signatory* that is responsible for adopting rules for initiating, implementing or enforcing any part of the *Doping Control* process. This includes, for example, the International Olympic Committee, the International Paralympic Committee, other *Major Event Organizations* that conduct *Testing* at their *Events*, WADA, International Federations, and *National Anti-Doping Organizations*.

Athlete: For purposes of *Doping Control*, any *Person* who participates in sport at the international level (as defined by each International Federation) or national level (as defined by each *National Anti-Doping Organization*) and any additional *Person* who participates in sport at a lower level if designated by the *Person's National Anti-Doping Organization*. For purposes of anti-doping information and education, any *Person* who participates in sport under the authority of any *Signatory*, government, or other sports organization accepting the *Code*.

Athlete Support Personnel: Any coach, trainer, manager, agent, team staff, official, medical or para-medical personnel working with or treating *Athletes* participating in or preparing for sports competition.

Athlete Comment: This definition makes it clear that all international and national-calibre athletes are subject to the anti-doping rules of the *Code*, with the precise definitions of international and national level sport to be set forth in the anti-doping rules of the International Federations and *National Anti-Doping Organizations*, respectively. At the national level, anti-doping rules adopted pursuant to the *Code* shall apply, at a minimum, to all persons on national teams and all

persons qualified to compete in any national championship in any sport. The definition also allows each *National Anti-Doping Organization*, if it chooses to do so, to expand its anti-doping control program beyond national-calibre athletes to athletes at lower levels of competition. Athletes at all levels of competition should receive the benefit of anti-doping information and education.

Attempt: Purposely engaging in conduct that constitutes a substantial step in a course of conduct planned to culminate in the commission of an anti-doping rule violation. Provided, however, there shall be no anti-doping rule violation based solely on an *Attempt* to commit a violation if the *Person* renounces the attempt prior to it being discovered by a third party not involved in the *Attempt*.

Code: The World Anti-Doping Code.

Competition: A single race, match, game or singular athletic contest. For example, the finals of the Olympic 100-meter dash. For stage races and other athletic contests where prizes are awarded on a daily or other interim basis the distinction between a *Competition* and an *Event* will be as provided in the rules of the applicable International Federation.

Consequences of Anti-Doping Rules Violations: An *Athlete's* or other *Person's* violation of an anti-doping rule may result in one or more of the following: (a) **Disqualification** means the *Athlete's* results in a particular *Competition* or *Event* are invalidated, with all resulting consequences including forfeiture of any medals, points and prizes; (b) **Ineligibility** means the *Athlete* or other *Person* is barred for a specified period of time from participating in any *Competition* or other activity or funding as provided in Article 10.9; and (c) **Provisional Suspension** means the *Athlete* or other *Person* is barred temporarily from participating in any *Competition* prior to the final decision at a hearing conducted under Article 8 (Right to a Fair Hearing).

Disqualification: See *Consequences of Anti-Doping Rules Violations* above.

Doping Control: The process including test distribution planning, *Sample* collection and handling, laboratory analysis, results management, hearings and appeals.

Event: A series of individual *Competitions* conducted together under one ruling body (e.g., the Olympic Games, FINA World Championships, or Pan American Games).

In-Competition: For purposes of differentiating between *In-Competition* and *Out-of-Competition Testing*, unless provided otherwise in the rules of an International Federation or other relevant *Anti-Doping Organization*, an *In-Competition* test is a test where an *Athlete* is selected for testing in connection with a specific *Competition*.

Independent Observer Program: A team of observers, under the supervision of WADA, who observe the *Doping Control* process at certain *Events* and report on observations. If WADA is testing *In-Competition* at an *Event*, the observers shall be supervised by an independent organization.

Ineligibility: See *Consequences of Anti-Doping Rules Violations* above.

International Event: An *Event* where the International Olympic Committee, the International Paralympic Committee, an International Federation, a *Major Event Organization*, or another international sport organization is the ruling body for the *Event* or appoints the technical officials for the *Event*.

International-Level Athlete: *Athletes* designated by one or more International Federations as being within the *Registered Testing Pool* for an International Federation.

International Standard: A standard adopted by WADA in support of the *Code*. Compliance with an *International Standard* (as opposed to another alternative standard, practice or procedure) shall be sufficient to conclude that the procedures addressed by the *International Standard* were performed properly.

In-Competition Comment: The distinction between "In-Competition" and "Out-of-Competition" testing is significant because the full *Prohibited List* is only tested for "In-Competition." *Prohibited stimulants*, for example, are not tested for *Out-of-Competition* because they have no performance enhancing benefit unless they are in

the *Athlete's* system while the *Athlete* is actually competing. So long as the *prohibited stimulant* has cleared the *Athlete's* system at the time the *Athlete* competes, it makes no difference whether that stimulant could have been found in the *Athlete's* urine the day before or the day after the *Competition*.

Major Event Organizations: This term refers to the continental associations of *National Olympic Committees* and other international multi-sport organizations that function as the ruling body for any continental, regional or other *International Event*.

Marker: A compound, group of compounds or biological parameters that indicates the *Use* of a *Prohibited Substance* or *Prohibited Method*.

Metabolite: Any substance produced by a biotransformation process.

Minor: A natural *Person* who has not reached the age of majority as established by the applicable laws of his or her country of residence.

National Anti-Doping Organization: The entity(ies) designated by each country as possessing the primary authority and responsibility to adopt and implement anti-doping rules, direct the collection of *Samples*, the management of test results, and the conduct of hearings, all at the national level. If this designation has not been made by the competent public authority(ies), the entity shall be the country's *National Olympic Committee* or its designee.

National Event: A sport *Event* involving international or national-level *Athletes* that is not an *International Event*.

National Olympic Committee: The organization recognized by the International Olympic Committee. The term *National Olympic Committee* shall also include the National Sport Confederation in those countries where the National Sport Confederation assumes typical *National Olympic Committee* responsibilities in the anti-doping area.

No Advance Notice: A *Doping Control* which takes place with no advance warning to the *Athlete* and where the *Athlete* is continuously chaperoned from the moment of notification through *Sample* provision.

No Fault or Negligence: The *Athlete's* establishing that he or she did not know or suspect, and could not reasonably have known or suspected even with the exercise of utmost caution, that he or she had *Used* or been administered the *Prohibited Substance* or *Prohibited Method*.

No Significant Fault or Negligence: The *Athlete's* establishing that his or her fault or negligence, when viewed in the totality of the circumstances and taking into account the criteria for *No Fault or Negligence*, was not significant in relationship to the anti-doping rule violation.

Out-of-Competition: Any *Doping Control* which is not *In-Competition*.

Participant: Any *Athlete* or *Athlete Support Personnel*.

Person: A natural *Person* or an organization or other entity.

Possession: The actual, physical possession, or the constructive possession (which shall be found only if the *Person* has exclusive control over the *Prohibited Substance/Method* or the premises in which a *Prohibited Substance/Method* exists); provided, however, that if the *Person* does not have exclusive control over the *Prohibited Substance/Method* or the premises in which a *Prohibited Substance/Method* exists, constructive possession shall only be found if the *Person* knew about the presence of the *Prohibited Substance/Method* and intended to exercise control over it. Provided, however, there shall be no anti-doping rule violation based solely on *possession* if, prior to receiving

Possession Comment: Under this definition, steroids found in an *Athlete's* car would constitute a violation unless the *Athlete* establishes that someone else used the car; in that event, the Anti-Doping Organization must establish that, even though the *Athlete* did not have exclusive control over the car, the *Athlete* knew about the steroids and

intended to have control over the steroids. Similarly, in the example of steroids found in a home medicine cabinet under the joint control of an *Athlete* and spouse, the Anti-Doping Organization must establish that the *Athlete* knew the steroids were in the cabinet and that the *Athlete* intended to exercise control over the steroids.

notification of any kind that the *Person* has committed an anti-doping rule violation, the *Person* has taken concrete action demonstrating that the *Person* no longer intends to have *Possession* and has renounced the *Person's* previous *Possession*.

Prohibited List: The List identifying the *Prohibited Substances* and *Prohibited Methods*.

Prohibited Method: Any method so described on the *Prohibited List*.

Prohibited Substance: Any substance so described on the *Prohibited List*.

Provisional Hearing: For purposes of Article 7.5, an expedited abbreviated hearing occurring prior to a hearing under Article 8 (Right to a Fair Hearing) that provides the *Athlete* with notice and an opportunity to be heard in either written or oral form.

Provisional Suspension: See *Consequences* above.

Publicly Disclose or Publicly Report: To disseminate or distribute information to the general public or persons beyond those persons entitled to earlier notification in accordance with Article 14.

Registered Testing Pool: The pool of top level *Athletes* established separately by each International Federation and National Anti-Doping Organization who are subject to both *In-Competition* and *Out-of-Competition Testing* as part of that International Federation's or Organization's test distribution plan.

Sample Specimen: Any biological material collected for the purposes of *Doping Control*.

Registered Testing Pool Comment: Each International Federation shall clearly define the specific criteria for inclusion of *Athletes* in its Registered Testing Pool. For example, the

criteria could be a specified world ranking cut-off, a specified time standard, membership on a national team, etc.

Signatories: Those entities signing the *Code* and agreeing to comply with the *Code*, including the International Olympic Committee, International Federations, International Paralympic Committee, *National Olympic Committees*, National Paralympic Committees, *Major Event Organizations*, *National Anti-Doping Organizations*, and WADA.

Tampering: Altering for an improper purpose or in an improper way; bringing improper influence to bear; interfering improperly to alter results or prevent normal procedures from occurring.

Target Testing: Selection of *Athletes* for *Testing* where specific *Athletes* or groups of *Athletes* are selected on a non-random basis for *Testing* at a specified time.

Team Sport: A sport in which the substitution of players is permitted during a *Competition*.

Testing: The parts of the *Doping Control* process involving test distribution planning, *Sample* collection, *Sample* handling, and *Sample* transport to the laboratory.

Trafficking: To sell, give, administer, transport, send, deliver or distribute a *Prohibited Substance* or *Prohibited Method* to an *Athlete* either directly or through one or more third parties, but excluding the sale or distribution (by medical personnel or by *Persons* other than an *Athlete's Support Personnel*) of a *Prohibited Substance* for genuine and legal therapeutic purposes.

Use: The application, ingestion, injection or consumption by any means whatsoever of any *Prohibited Substance* or *Prohibited Method*.

WADA: The World Anti-Doping Agency.

The role of measurement uncertainty in doping analysis

Elena Spirito* and Francesco Botrè

Laboratorio Antidoping, Federazione Medico Sportiva Italiana,

*Corresponding author

Abstract: The determination of measurement uncertainty is a critical issue in all fields of experimental science; its importance becomes maximal in the specific case of forensic analytical chemistry (including doping analysis), where uncertainty has not only to be calculated with precision, but it also has to be both small and reliable enough to support effective decision making. This contribution gives a general view of the organisation of the activity of the network of the anti-doping laboratories accredited by the World AntiDoping Agency (WADA), focusing in particular on the current situation related to the determination of measurement uncertainty in doping analysis. Representative examples referring to the procedures followed in the case of threshold substances are also presented and discussed.

Keywords: anabolic steroids; doping analysis; nandrolone; norandrosterone; testosterone; testosterone/epitestosterone ratio; uncertainty.

Reference to this paper should be made as follows: Spirito, E. and Botrè, F. (2005) 'The role of measurement uncertainty in doping analysis', *Int. J. Risk Assessment and Management*, Vol. 5, Nos. 2/3/4, pp.374–386.

Biographical notes: Elena Spirito, Dr Eng in Chemical Engineering, is Quality Manager of the Antidoping Laboratory of Rome, Italy, accredited ISO 17025 and by the World AntiDoping Agency (WADA). Her main field of study is focused on the validation and uncertainty evaluation and assessment of instrumental analytical methods, with experience as a Consultant Engineer in the area of environmental impact of engineering technologies and of quality control for design activities in the field of composite structures production.

Francesco Botrè, Dr in Chemistry and in Pharmaceutical Sciences, post-degree specialisation in experimental pharmacology. He is Professor of pharmacokinetics and of ecology at the University of Rome 'La Sapienza'; Scientific Director of the Antidoping Laboratory of Rome, Italy; and Fellow of the World Association of Antidoping Scientists (WAADS). He is also a Member of several scientific societies and of the editorial board of international scientific journals, and author of over 200 scientific publications, including review articles and books, in the fields of biochemical analysis, physiopharmacology and environmental science.

1 Introduction: the activity and organisation of anti-doping laboratories

The control of the illicit use of performance enhancing substances and methods in sport is carried out by a network of anti-doping laboratories accredited by the World Anti-Doping Agency (WADA), that is the international authority responsible for the anti-doping regulation (World Antidoping Agency, 2004a). In this context, the role of the anti-doping laboratories is to detect the presence, in the athlete's body, of any of the doping substances and/or their metabolites and/or markers of administration whose use is prohibited by WADA itself. All prohibited substances and methods are included in a list that is periodically updated and that, at present, comprises over 200 substances (World Antidoping Agency, 2003).

To carry out an anti-doping test means to select the athlete(s) to be tested, to collect, either 'in competition' or 'out of competition', a suitable amount of biological sample (generally urine, with the use of blood limited to the search of specific parameters), to deliver it to the laboratory under a strict chain of custody, where it is analysed – without any reference to the identity of the athlete(s) – according to internationally recognised methods, to detect the putative use of prohibited substances and methods.

Unlike what happens in other areas of analytical chemistry, laboratories are not involved in the sampling procedures: they do not have any role in the selection of the athletes to be tested, in the collection of the biological samples and in their transport to the laboratory. In other words, the forensic nature of the analytical measurement imposes a strict control on all the different stages of the testing process, including those occurring out of the anti-doping laboratory.

At present, there are 33 laboratories accredited by the WADA in the world (Table 1), analysing 200,000 urine/blood samples per year, with a positivity level oscillating around 2% (see www.wada-ama.org for details).

Table 1 The anti-doping laboratories accredited by the World Anti-Doping Agency (last update: February 2005)

| | |
|----------|---|
| Africa | South Africa (<i>Bloemfontein</i>), Tunisia (<i>Tunis</i>) |
| Americas | Brazil (<i>Rio de Janeiro</i>), Canada (<i>Montreal</i>), Colombia (Bogota), Cuba (<i>La Habana</i>), USA (<i>Los Angeles</i>) |
| Asia | China (<i>Beijing</i>), Korea (<i>Seoul</i>), Japan (<i>Tokyo</i>), Malaysia (<i>Penang</i>), Thailandia (<i>Bangkok</i>) |
| Europe | Austria (<i>Seibersdorf</i>), Belgium (<i>Ghent</i>), Czech Republic (<i>Prague</i>), Finland (<i>Helsinki</i>), France (<i>Paris</i>), Germany (<i>Cologne, Kreischka</i>), Greece (<i>Athens</i>), Italy (<i>Rome</i>), Norway (<i>Oslo</i>), Poland (<i>Warsaw</i>), Portugal (<i>Lisbon</i>), Russian Federation (<i>Moscow</i>), Spain (<i>Barcelona, Madrid</i>), Sweden (<i>Stockholm</i>), Switzerland (<i>Lausanne</i>), Turkey (<i>Ankara</i>), UK (<i>Cambridge, London</i>) |
| Oceania | Australia (<i>Sydney</i>) |

Since it is self-evident that a wrong laboratory result, apart from a merely scientific point of view, can have dramatic consequences on the credibility of the whole anti-doping system, many actions have been undertaken, at different levels, to guarantee the solidity of the experimental data.

In particular:

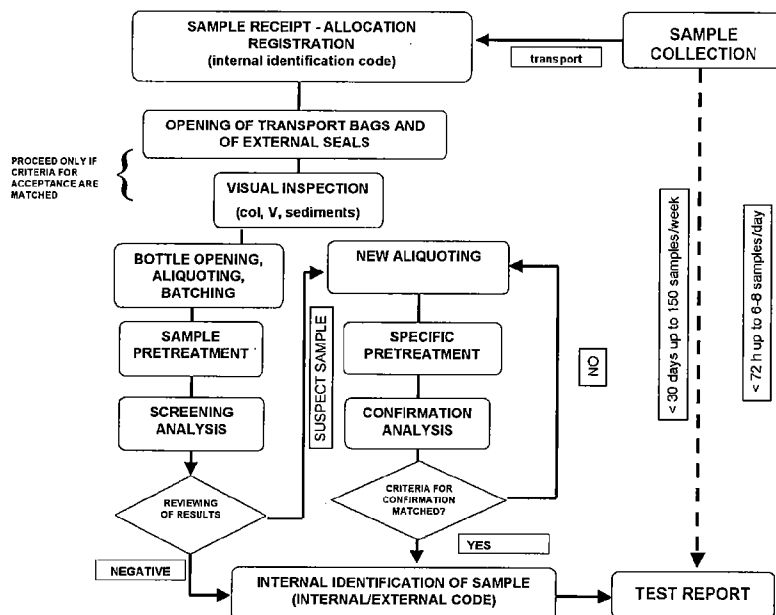

- laboratories have to achieve and maintain ISO 17025 accreditation
- laboratories have to comply with the WADA specific requirements (international standards) (World Antidoping Agency, 2004b)
- samples are sent to the laboratory under a strict chain of custody
- the laboratory is unaware of the identity of the tested athletes
- any adverse analytical finding can be verified by re-analysing a second aliquot of the sample, in the presence of the athlete and of a technical expert.

In the first two points of the above list, and in the correlated technical documents, are included all the requirements the laboratories have to satisfy to gain and maintain the status of a WADA accredited laboratory. More precisely, ISO 17025 accreditation is a prerequisite for all WADA laboratories.

The usual analytical procedure which is followed by all WADA laboratories for all prohibited substances is constituted by two stages: a series preliminary testing (screening), carried out on the whole population of samples to be assayed and the subsequent confirmation analysis, carried out only on those samples which gave positive or even doubtful results after the screening. In the case of threshold substances, laboratories are obliged to follow a validated procedure to assess the degree of confidence of their measurement.

Figure 1 schematically represents the organisation of the internal procedures at the anti-doping laboratory of Rome, Italy.

Figure 1 Block diagram summarising the general organisation of the workflow at the anti-doping laboratory of Rome, Italy

2 Measurement uncertainty and doping analysis

Measurement uncertainty defines a range of values containing the true value. It is self-evident that the determination of measurement uncertainty is a critical issue in all fields of experimental science; its importance becomes maximal in the specific case of forensic analytical chemistry (including doping analysis), where uncertainty has not only to be calculated with precision, but it also has to be both small and reliable enough to support effective decision making.

Historically, the assessment of measurement uncertainty was originally limited to the areas of clinical chemistry and laboratory medicine, pharmaceutical analysis, food and environmental analysis and materials characterisation; recently, inter-laboratory studies aimed at quantifying and improving the reproducibility of measurements have been focused also on forensic assays, commodity testings and biotechnology, including DNA profiling and the control of genetically modified organisms.

Unlike what common sense may suggest, the main job of an anti-doping laboratory is not the protection of the health of an athlete: the aim of the analysis, to maintain the language of forensic science, is 'to supply evidence'. The main differences between 'traditional' clinical chemistry and anti-doping laboratories are highlighted in Table 2.

Table 2 Main differences between clinical and anti-doping tests

Clinical chemistry

- matrices: the most suitable biological material
- aim: diagnostic tests
- test report can be based on:
 - detection and quantitation of diagnostic markers
 - multiparametric profiles
- a doubtful sample can be treated as a positive one (activating further investigation).

Doping control analysis

- matrices: only urine for officially recognised tests
 - aim: to supply evidence
 - test report based on:
 - unambiguous identification of specific drugs/metabolites
 - a doubtful sample is generally treated as a negative one (no further investigation).
-

The logical process to be followed in the determination of measurement uncertainty – including doping analysis – is the following (Ellison et al., 2000): preliminarily, a relationship between the measurand and the parameters upon which it depends has to be defined; secondly, all possible sources of uncertainty have to be identified at all stages of the analytical process; then the specific uncertainty for each one of the above-mentioned stages has to be calculated and converted to standard uncertainties; the latter have to be expressed as variances (to avoid false counterbalancing), then

combined and, finally, the resulting overall uncertainty has to be indicated as 'expanded uncertainty', to ensure the desired confidence level (e.g. 99%).

Anti-doping analysis is a good example of a field where the assessment of measurement uncertainty deserves a dedicated examination. Since none of the anti-doping laboratory methods can be considered a primary method of measurement (i.e. a method having the highest metrological qualities, whose operation can be completely described and understood, for which a complete uncertainty statement can be written down in terms of SI units), it follows that traceability is mandatory.

As stated before, the anti-doping analyses may be performed only by accredited laboratories; this means that they have to be accredited both according to the ISO 17025 and by the World Anti-Doping Agency; more precisely, ISO 17025 accreditation is a fundamental prerequisite to obtain and maintain the status of 'official' laboratory.

It may be significant to specify that, also according to the World Anti-Doping Code International Standard for Laboratories (World Antidoping Agency, 2004b), anti-doping laboratories do not define, in their test reports, a sample as 'positive' or 'negative', but instead report an 'adverse analytical finding'. This definition simply means that a sample was not found to be compliant: this non-compliance may be due to the simple presence of a banned substance, or, in the case of threshold substances, to a value of its concentration exceeding the threshold value itself (Van Eenoo and Delbeke, 2003).

The general expression used, for the determination of combined uncertainty of the variable $y = f(x_i)$ is the following:

$$u(y) = \sqrt{\sum_{i=1}^n \left(\frac{\partial y}{\partial x_i} \right)^2 u^2(x_i)} \quad (1)$$

where it is assumed that there is not any correlated effect among any of the x_i variables.

In practice, to report an adverse analytical finding, it is necessary to identify a prohibited substance, and, in the case of substances with a reporting threshold, to measure a value exceeding the threshold; in the latter case, it is mandatory to express the measurement uncertainty. It is not unusual for a result apparently exceeding the threshold, if taken as a single value or even as a mean value to not be correctly reported as 'above the threshold' if the measurement uncertainty is not taken into account. In Figure 2 it is evident that only case 'E' shows a value that is above the threshold also taking into account the measurement uncertainty.

Figure 2 The role of measurement uncertainty in correctly reporting a value 'above the threshold'

The application of these general principles is here discussed on the basis of the approach followed at the WADA-ISO 17025 anti-doping laboratory of Rome to calculate the measurement uncertainty on two specific procedures:

- the confirmation of nandrolone metabolites, and specifically of norandrosterone, whose urinary concentration threshold is fixed at 2 ng/ml
- the confirmation of an elevated testosterone/epitestosterone (T/E) concentration value, where the threshold has recently been reduced from 6 to 4.

3 Case studies

3.1 Case 1: norandrosterone (nandrolone metabolite): WADA cut off set at 2 ng/ml for a sample of normal density (specific gravity ≤ 1.020)

Following the qualitative identification of norandrosterone (NA), its concentration is measured by GC-MS, on the basis of the area ratio between the signal of NA (ion m/z 405) and that of norandrosterone d4 (NAd4), added as internal standard (ion m/z 409). The ratio NA/NAd4 in the sample is then compared to the same ratio in the positive reference urine, usually spiked with norandrosterone at the threshold value.

For each assayed aliquot, the ratio between the concentration of norandrosterone in the unknown sample (c_{sample}) and the concentration in the positive spiked urine (c_{USP}) is calculated using this formula:

$$Y = \frac{c_{sample}}{C_{USP}} = \frac{R_{ac}}{R_{au}} \quad (2)$$

where

$$R_{ac} = \frac{A_{cNA}}{A_{cNAd4}} \quad (3)$$

i.e. the area ratio between NA and NAd4 in the sample, and

$$R_{au} = \frac{A_{uNA}}{A_{uNAd4}} \quad (4)$$

i.e. the area ratio between NA and NAd4 in the positive reference urine.

In this case, $u(Y)$, that is relative the uncertainty (u), related to the measurement (Y) may be defined as

$$\frac{u(Y)}{Y} = \sqrt{\left(\frac{u_{Rac}}{Rac}\right)^2 + \left(\frac{u_{Rau}}{Rau}\right)^2} \quad (5)$$

where, in turn, Rac and Rau , representing the concentration ratios, are defined as follows:

$$Rac = \frac{x \cdot V_{ur}}{V_{pd} \cdot S_{md}} \quad (6)$$

$$Rau = \frac{S_m \cdot V_p}{V_{pd} \cdot S_{md}} \quad (7)$$

and x is the unknown concentration in the sample, V_{ur} the urine sampled volume, V_{pd} the internal standard sampled volume, S_{md} the internal standard concentration, S_m the standard solution concentration and V_p the standard sampled volume.

R_{ac} and R_{au} uncertainties can now be defined as follows:

$$\frac{u_{R_{ac}}}{R_{ac}} = \sqrt{\left(\frac{u_{V_{ur}}}{V_{ur}}\right)^2 + \left(\frac{u_{S_{md}}}{S_{md}}\right)^2 + \left(\frac{u_{V_{pd}}}{V_{pd}}\right)^2} \quad (8)$$

$$\frac{u_{R_{au}}}{R_{au}} = \sqrt{\left(\frac{u_{V_p}}{V_p}\right)^2 + \left(\frac{u_{S_m}}{S_m}\right)^2 + \left(\frac{u_{S_{md}}}{S_{md}}\right)^2 + \left(\frac{u_{V_{pd}}}{V_{pd}}\right)^2} \quad (9)$$

In addition to the above, we can finally consider other two uncertainty fonts, namely the area ratio repeatability and the method linearity. The composed uncertainty of the ratio is therefore given by:

$$u(Y)_{comp} = \sqrt{u(Y)^2 + u_{rip}^2 + u_{lin}^2} \quad (10)$$

where u_{rip} = areas ratio repeatability uncertainty calculated during the analysis and u_{lin} = uncertainty related to the linearity of the validated method (i.e. residual standard deviation).

3.2 Case 2: norandrosterone (nandrolone metabolite): correction to apply in the case of a sample with elevated density (specific gravity > 1.020)

In the case of samples with a specific gravity higher than 1.020, the NA concentration threshold of 2 ng/ml has to be increased proportionally to the value of the specific gravity. This means that, in this case, a further source of uncertainty is present, deriving from the measurement of the specific gravity of the sample. This contribution may be incorporated in the overall uncertainty as follows: first of all it is necessary to rewrite Equation (2) taking into account this correction:

$$Y^I = \frac{R_{ac}}{R_{au}^I} \quad (11)$$

where

$$R_{au}^I = \frac{(\rho_c - 1)R_{au}}{0.02} \quad (12)$$

so that Equation (11) becomes

$$Y^I = \frac{0.02R_{ac}}{R_{au}(\rho_c - 1)} \quad (13)$$

The overall relative uncertainty (previously given by Equation (5)) is now given by

$$\frac{u(Y^I)}{Y^I} = \sqrt{\left(\frac{u_{R_{ac}}}{R_{ac}}\right)^2 + \left(\frac{u_{R_{au}}}{R_{au}}\right)^2 + \left(\frac{u_{\rho_c}}{\rho_c - 1}\right)^2} \quad (14)$$

where ρ_c is the sample specific gravity and u_{ρ_c} is the uncertainty associated to ρ_c .

Finally, the composed uncertainty of the corrected ratio is given by:

$$u(Y^I)_{comp} = \sqrt{u(Y^I)^2 + u_{rip}^2 + u_{lin}^2} \quad (15)$$

with u_{rip} and u_{lin} defined as in Equation (10).

In the case of a positive reference urine spiked with NA at a final concentration of 2 ng/ml, the concentration of NA in the sample is reported as 'above the threshold' whenever the mean value of Y (or Y^I in the case of a value of the specific gravity > 1.020), subtracted of its expanded uncertainty $U(Y)$ – or $U(Y^I)$ in the case of specific gravity > 1.020 , is still greater than 1, with $U(Y)$ and $U(Y^I)$ defined as follows:

$$u(Y)_{ex} = k \cdot u(Y)_{comp} \quad (16)$$

$$u(Y^I)_{ex} = k \cdot u(Y^I)_{comp} \quad (17)$$

where k defines the coverage factor.

3.3 Case 3: elevated testosterone/epitestosterone concentration ratio

Testosterone is an androgenic anabolic steroid, naturally synthesised by the body and excreted in the urine mainly as glucuronate. A reliable index of synthetic testosterone administration is the value of the concentration ratio between testosterone and its natural epimer, epitestosterone: the value of this ratio is usually around 1 and is, however, quite constant over time for the same subject. An abnormally elevated value of the testosterone/epitestosterone (T/E) concentration ratio is considered sufficient to drive further investigations, these being either longitudinal tests and/or endocrinological investigation (to assess whether the elevated value of the T/E ratio may be traced to physio-pathological causes) and/or advanced physico-chemical tests, e.g. GC-(C)IRMS, gas chromatography coupled to combustion isotopic ratio mass spectrometry.

From a general point of view, testosterone and epitestosterone concentrations in the urine sample are quantified, also in this case by GC-MS; the ion m/z 432 is monitored for both target compounds, eluting at different retention times.

A calibration curve, based on at least three points, is drawn for both T and E; the general equation of this (linear) calibration curve can be written as

$$Y = BX + Q \quad (18)$$

where

$$Y = \frac{A_c}{A_{deut}} \quad (19)$$

is the ratio between the area of the target compound and that of its specific internal standard (usually its deuterated isotope), and

$$X = \frac{x_c}{x_{deut}} \quad (20)$$

is the ratio between the concentration of the target compound and that of its deuterated internal standard.

It follows that the concentration of the target compound in the sample is given by:

$$x_c = \frac{(Y - Q)}{B} x_{deut}. \quad (21)$$

According to the WADA International Standard for Laboratories and the relevant technical documents, the laboratory reports an adverse analytical finding whenever the value of the concentration ratio between testosterone and epitestosterone is greater than 4.

As can be seen, to take into account the measurement uncertainty in this case is more complex than for the norandrosterone concentration, since the concentrations of two different compounds have to be measured in the sample and their values have also to be somehow correlated. In this case, one possible approach would be to determinate the concentrations of T and E separately and then to calculate the corresponding concentration ratio. The first step is to determine the concentration ratio between the target compound (T or E) and its deuterated internal standard. The uncertainty of this value depends on two separate sources: the repeatability uncertainty, u_r , and the calibration curve uncertainty, u_c . These contributions can be linked by the following relation, to give the overall uncertainty, u_X :

$$u_X = \sqrt{u_r^2 + u_c^2}. \quad (22)$$

Let us now consider the two components of the right hand term of the above equation separately.

3.3.1 Repeatability uncertainty U_r

Two cases can be distinguished and considered independently.

Firstly, the validation has demonstrated that there is a significant difference on repeatability between the instrumental injection and aliquot preparation, with the latter larger than the former. In this case the repeatability uncertainty is defined as

$$u_r = \sqrt{\frac{S_{ILT}^2}{h} + \frac{S_r^2}{hk}} \quad (23)$$

where S_r^2 = injection contribution expressed as mean variance of each aliquot during validation process; h = number of aliquots prepared during the analysis; k = number of injection made during the analysis.

It can now be written:

$$S_{ILT} = S_{IMT}^2 - \frac{S_r^2}{n} \quad (24)$$

where, in turn, S_{IMT}^2 = sample preparation contribution expressed as variance of the aliquot means; n = number of injection during validation process.

Secondly, the validation has demonstrated that there is no significant difference on repeatability between instrumental injection and aliquot preparation. In this case the repeatability uncertainty is given by

$$u_r = \frac{S_{rt}}{\sqrt{N}} \quad (25)$$

where S_{ri} is the standard deviation of the validation total number of tests (aliquot and injections) and N is the total number (aliquot \times injections) of tests during the analysis.

3.3.2 Calibration curve uncertainty U_c

This component of the overall uncertainty is more complex to deal with; basically, the following equations apply:

$$s_{x0} = \frac{s_{y/x}}{b} \sqrt{\frac{1}{m} + \frac{1}{n} + \frac{(y_0 - \bar{y})^2}{b^2 \sum_i (x_i - \bar{x})^2}} \quad (26)$$

$$s_{y/x} = \sqrt{\frac{\sum_i (y_i - y_{ic})^2}{n - 2}} \quad (27)$$

where, b is the slope of the calibration curve; n is the number of curve points; \bar{y} is the mean value of calibration points; m is the number of reads for each sample; \bar{x} is the mean concentration of the calibration points; $s_{y/x}$ is the residual standard deviation and y_{ic} is the y value calculated using the curve at i point.

The results obtained by using the calibration curve are ratios between compound concentration x_c and internal standard x_{deut} and are given by

$$X = \frac{x_c}{x_{deut}} \quad (28)$$

Now, if, from the above equation, the concentration of the target compound is expressed as $x_c = X \cdot x_{deut}$, the compound concentration uncertainty u_c is given by:

$$u_c = \sqrt{X^2 u_{x_{deut}}^2 + x_{deut}^2 u_X^2} \quad (29)$$

where $u_{x_{deut}}$ is the uncertainty due to internal standard concentration in the sample ($x_{deut} = V_{Smd} * S_{md} / V_{ur}$) expressed as:

$$u_{x_{deut}} = x_{deut} \sqrt{\left(\frac{u_{V_{Smd}}}{V_{Smd}}\right)^2 + \left(\frac{u_{V_{ur}}}{V_{ur}}\right)^2} \quad (30)$$

where, again, S_{md} is the concentration of solution, $u_{V_{Smd}}$ is the uncertainty of the volume of solution sampled and $u_{V_{ur}}$ is the uncertainty of the volume of urine sampled.

3.3.3 Uncertainty on sampled volumes ($U_{V_{Smd}}$ and $U_{V_{ur}}$)

Sampled volumes uncertainty, u_{V_-} , is defined as follows:

$$U_{V_-} = \sqrt{u_r^2 + \left(\frac{u_d}{\sqrt{3}}\right)^2} \quad (31)$$

where u_r is the repeatability uncertainty and u_d is the certified uncertainty due to the glassware used.

3.3.4 Composed uncertainty on the value of the T/E concentration ratio

The contribution due to testosterone concentration and epitestosterone concentration, calculated as expressed above, must be combined using the function $Y = T/E$.

The related uncertainty is given by:

$$u(Y) = Y * \sqrt{\frac{u_T^2}{T^2} + \frac{u_E^2}{E^2}} \quad (32)$$

where u_T is the uncertainty on testosterone concentration (T) and u_E is the uncertainty on epitestosterone concentration (E).

3.3.5 Expanded uncertainty

Also in this case the expanded uncertainty is dependent on the chosen coverage factor k :

$$U_e = k u_e. \quad (33)$$

4 Conclusions

It may be interesting to compare the representative cases presented above with a generally applicable approach to the determination of relative uncertainty. Perhaps the most general relationship which correlates the measurement uncertainty (expressed as RSDR) to the expected concentration, C , of the analyte in the sample is given by the Horwitz equation (Horwitz et al., 1980):

$$\text{RSDR} = 2C^{-0.1505}. \quad (34)$$

The above relation has been drawn following a statistically significant number of inter-laboratory comparative studies that, although not involving the network of the accredited anti-doping laboratories, may be considered applicable also in this context.

The Horwitz function is often proposed in its graphical form: for indeed, plotting Equation (34) generates the so called 'Horwitz trumpet', reproduced in Figure 3.

Figure 3 The 'Horwitz trumpet' (plotted on the basis of Equation (34)), correlating the relative uncertainty (expressed as coefficient of variation %) to the expected concentration of analyte in the sample (Horwitz et al., 1980)

It may be interesting to stress that most of the anti-doping cases (and particularly the confirmation of nandrolone metabolites) lie in the aflatoxins-range ($2 \text{ ng/ml} = 2 \text{ ppb}$ is indeed the threshold value of norandrosterone, the main metabolite of nandrolone), characterised by an estimated uncertainty of roughly 40–45%. According to the data represented above, confirmed also by other studies (Van Eenoo and Delbeke, 2003), the uncertainty of the anti-doping laboratories closely match with the Horwitz figures, being in most cases even lower than that expected.

A final comment concerns some economical considerations: it is self-evident that a thoughtful consideration of measurement uncertainty is a critical issues in all areas of analytical chemistry, especially whenever the experimental results are discussed on forensic grounds. However, it must be understood that precision is not cheap: as a general trend, the uncertainty associated with a laboratory method is inversely proportional to the cost of the method itself (Figure 4). In general, technological innovation, professional expertise and technical skill can drive a more or less pronounced shift of the curve towards the origin, but nonetheless the general trend is qualitatively the same for all methods.

Figure 4 The inversely proportional relationship that defines that increasing economical resources are necessary to reduce the uncertainty of measurement

In this sense, the recent reorganisation of anti-doping regulations given by the WADA and, at the same time, the activity of the network of the accredited laboratories, carried out mainly by the World Association of Anti-Doping Scientists (WAADS) ensure that all methods followed by the laboratories are 'fit to purpose', the latter being to provide 'clear and convincing' evidence of any detectable doping offence based on an adverse analytical finding.

Appendix D: Error List

This is a list of apparently obvious documentation errors: record keeping errors, simple math errors, or obvious errors in procedure. This list does not address scientific principles or the validity of conclusions. Many of the pages in the document package are boiler-plate machine printed protocols. Most of the pages listed below are handwritten errors.

| Page | ISO Violated? | Errors | Issues | Comments |
|--------------------|---------------|--------|--------------------------------------|--|
| USADA Notice | | 2 | Type Lab | The notice for 995474 is listed as "Out of Competition" The WADA accredited lab is listed as "University of California at Los Angeles" |
| USADA0004 | | 2 | Sample ID Calculation | A partial lab identification number or sample number has been crossed out without initial or date. Specific gravity calculation not based on 0.8 (1.020 vs. 1.025). |
| USADA0007 | | 2 | Cross-out Value | Cross-out on last line. Specific gravity is listed here as 1.026. Everywhere else, it is listed as 1.025. |
| USADA0008 | Yes | 1 | Sample ID | In the middle of the page, second column, a sample is listed as 995475. Floyd's 17th stage number was 955474. This page is missing in the AFLD filing. This may be an effort to cover-up this error and malfeasance. |
| USADA0009 | Yes | 1 | | There has been a correction of number from 992474 to 995474. |
| USADA0024 | Yes | 3 | Sample ID Time/date Cross-outs | Floyd's sample/sample number is not properly recorded as having been transported. Handwriting legibility: a 6 vs. a 4? The LNDD reception time is 9h35. It should be listed as 21h35 or 9:35 PM. There is an overwriting of blood specimen 149986. There is a cross out in the bottom left signature. |

United States Anti-Doping Agency,

Claimant,

v.

Floyd Landis,

Respondent.

**DECLARATION OF SIMON
DAVIS**

AAA No. 30 190 00847 06

I, Simon Davis, declare:

1. I am the Technical Director of MS Solutions. I make this declaration based on my personal knowledge, and if called as a witness, I could and would testify competently to the matters set forth herein.
2. I received a Bachelor of Science Honours in Environmental Biology from Oxford Brookes University in 1991. I received a Ph.D. in Stable Isotope Mass Spectrometry from Liverpool JMU, in association with Cambridge University, in 1996.
3. I was a Stable Isotope Systems Engineer for Micromass UK Ltd. from May 1997 to July 1998. From July 1998 to June 2000, I was a Staff Scientist at the Lawrence Berkley National Laboratory, Berkley University. I rejoined Micromass UK Ltd. as a Development Project Leader for the Inorganic MS Group from June 2000 to March 2003. From March 2003 to March 2005, I was a Research Officer for Queens University. In March 2005, I joined MS Solutions as the Technical Director.

4. Based on my education and experience, I am familiar with the testing commonly used in anti-doping detection: The Testosterone to Epitestosterone ratio test ("T/E test") and the Carbon Isotope Ratio test ("CIR").
5. The T/E test is performed using a Gas Chromatography/Mass Spectrometer ("GC/MS") instrument, which calculates the ratio of testosterone to epitestosterone in a sample. The T/E test calculates this ratio by comparing the specific ion signal – called a "response" – of testosterone to the response of epitestosterone.
6. The GC/MS cannot distinguish between synthetic and natural testosterone, however, because their mass spectra are identical. Epitestosterone is an inert epimer of testosterone, which means that it has the same chemical makeup as testosterone, but because of a difference in chirality (a geometric difference – sort of a mirror image) at one location, epitestosterone is not biologically active.
7. In theory, the ratio of testosterone to epitestosterone in urine in adult males should be approximately 1:1. In fact, however, ratios as high as 15:1 or higher could be normal; conversely, some individuals naturally have low urinary T/E ratios that do not change even with the administration of exogenous testosterone.
8. I am also familiar with the CIR, which also has been described as the test for "synthetic testosterone." Generally, molecules are composed of atoms; specifically, biological molecules are composed primarily of Carbon, Oxygen and Hydrogen atoms. Carbon, in its basic form, is an atom composed of six electrons, six protons and six neutrons. In nature, however, most atoms have one or more stable isotopes. A stable isotope is an atom that has "extra" neutrons. In the case of carbon, ^{13}C is a stable isotope that has one "extra" neutron. The actual carbon isotope makeup of any

individual will vary based on his or her diet. The same is true for plants. As it turns out, the particular plants (mostly soy) used for the building blocks of synthetic or pharmaceutical testosterone are particularly low in ^{13}C , especially when compared to the levels found in most humans.

9. The CIR test is performed using an IRMS instrument, which measures the ratio of $^{13}\text{C}/^{12}\text{C}$ in a target analyte. The theory behind the test is that synthetic testosterone, which is usually soy-based, will be depleted in carbon 13. To account for individual variabilities in things such as diet, which can affect the $^{13}\text{C}/^{12}\text{C}$ ratio, the test compares the $^{13}\text{C}/^{12}\text{C}$ ratio of a testosterone metabolite that is believed to be affected by exogenous testosterone to the $^{13}\text{C}/^{12}\text{C}$ ratio of an endogenous reference compound that is believed not to be affected by exogenous testosterone. By comparing the difference in the $^{13}\text{C}/^{12}\text{C}$ ratio between a testosterone metabolite and a testosterone precursor, or other endogenous reference compound, the CIR test can determine the likelihood of testosterone being from an exogenous source.
10. In theory, for any individual at any one time the $^{13}\text{C}/^{12}\text{C}$ ratio of a testosterone precursor should be identical (or very close) to that of a testosterone metabolite. If a person is using exogenous testosterone, however, there will be a detectable and significant difference between the $^{13}\text{C}/^{12}\text{C}$ ratio in a testosterone metabolite and a testosterone precursor. In other words, if a person is taking exogenous testosterone, his or her $^{13}\text{C}/^{12}\text{C}$ ratio for a testosterone metabolite will be different than the ratio for a testosterone precursor.

11. Once the $^{13}\text{C}/^{12}\text{C}$ ratio, commonly reported in the delta per mil notation ($\delta^{13}\text{C}\text{‰}$), for the testosterone metabolites is calculated, the ratio can be compared with the positivity criteria mandated by the World Anti-Doping Agency.

12. In conjunction with this case, I have reviewed Laboratoire National de Depistage du Dopage's (LNDD) laboratory document package concerning Floyd Landis. I have also reviewed the United States Anti-Doping Agency's responses to Mr. Landis's Second Request for Production.

13. I have relied upon the documents referenced above, my education, my experience, and generally accepted principles within the scientific community in reaching the following conclusions:

- a. The Optima GC 1.67-2 software was originally written for the Micromass Optima IRMS and not the Isoprime IRMS instrument. This software is now 10 years old and can be identified by its code number 1.67-2.
- b. Since version 1.67-2 of software was produced, there have been six major version releases of software for the Isoprime. These include (1) Version 1.67-3 (OS2 operating system) (2) Version 1.67-4 (OS2 operating system), (3) Masslynx Version 3.5i (Windows NT), (4) Masslynx Version 3.6i (Windows NT), (5) Masslynx Version 4.0 (Windows XP) and (6) Ion Vantage Version 1.0 (Windows XP).
- c. The newer versions of the software have the following improvements:
 - i. The newer software includes a new set of electronics with a new set of firmware for the systems head amplifier that corrected errors in the OS2 head amplifier firmware.

- ii. The newer software has the ability to control the GC portion of the GC-C-IRMS, whereas in the OS2 versions of the software, the operator has to manually program the GC.
- iii. The newer software traces any changes that are made to the data post acquisition. For instance, if the software is reprocessed with different integration parameters this would be recorded in all Masslynx and Ion vantage systems, but not in any OS2 systems.
- iv. The newer software contains a standards library, for the automated storage and retrieval of standards values and data. OS2 requires the standards to be applied manually post acquisition.
- v. The newer software has fully documented and tested background subtraction routines. The method and validity of the background routines in the OS2 software is unknown and undocumented. All documentation of the OS2 routines was lost when Micromass purchased Isotech (the developers of the original software).
- vi. The newer software has improved peak detection – the true nature of the OS2 detection methods is unknown as no documentation remains as to the method used.
- vii. The newer software provides “read-backs” that allow the true state of the Isoprime to be observed and recorded. The OS2 system offers no read backs.
- viii. The newer software works on a modern operating system for which you can obtain up-to-date anti-virus and malware software. OS2 Warp

(the latest software that version 1.67-2 will run on) is no longer supported by IBM and no anti-virus or security software is available.

ix. The newer software is compatible with a number of Laboratory Integrated Management Systems. This is used for the control of results management.

d. On account of the age of the software, and the fact that it was not designed for this specific IRMS instrument, there is a serious question about whether it is capable of delivering consistently accurate results.

e. If the new software were used, it would provide better peak detection, tested and documented background subtraction routines and would remove any errors in the head amplifier firmware. It would also provide a stable and modern operating system with up to date anti-virus and other security software.

f. Production of the Electronic Data Files ("EDFs") is necessary for the fair adjudication of this matter because the EDFs will assist Mr. Landis' experts in determining whether errors in reporting the results may have stemmed from:

- i. Errors in the Isoprime head amplifier software.
- ii. Incorrect and wrongly applied background subtraction.
- iii. Poor peak integration.
- iv. Inappropriate reprocessing of the original data files.

g. Moreover, if the EDFs are provided, it will be possible to identify if the data reported by the laboratory has been reprocessed. Although the OS2 software does not provide a traceable audit of any reprocessing, it is possible to extract

the original raw data which can then be compared to those results reported by the LNDD.

14. As to the use and maintenance of a GC-IRMS instrument, I have consulted my copy of the Isoprime User Manual, which I have given to Mr. Landis and his counsel. The Isoprime User Manual states that the operating pressure for the GC-IRMS instrument is between 2 and 4E-6 mbar.

15. I have also reviewed USADA 0176 and confirmed that it shows that the GC-IRMS instrument was operating at a pressure of 5.2E-6.

16. I have relied upon the Isoprime User Manual and USADA 0176, my education, my experience, and generally accepted principles within the scientific community in reaching the following conclusions:

- a. Operating the GC-IRMS instrument at pressures of 5E-6 millibars or above can result in reduced sensitivity and precision of the reported results and increased variance values. All mass spectrometers require a vacuum in order to operate properly, which involves ensuring that the ion beam can pass from the source to the detector system in a manner consistent with the manufacturer's specifications.
- b. Failure to operate this machine properly can result in (1) false detection of atmosphere gas as analyte gas and (2) competitive ionization that results in the reduction of the sensitivity of the instrument to analyte gas, among others problems.

- c. Additionally, the increased pressure recorded in the Penning gauge possibly resulted from increased helium pressure in the GC-C system, causing similar defects in results.
- d. The increased pressure will result in a decreased lifespan of the source filament, which also may increase the reported measure of variance.

I declare under penalty of perjury under the laws of the State of California that the foregoing is true and correct and that this declaration was executed on February __, 2007 in 13th of February

Simon Davis

IsoPrime EA User Manual

IsoPrime-EA User Manual

This manual provides the operation and maintenance instructions for the IsoPrime-EA. This will include details on the IsoPrime mass spectrometer with the elemental analyser and interface. We have endeavoured to include all operational aspects within this manual, however if you feel more information is required or that you can add some more details, then please contact the Customer Service Department at Micromass UK Ltd. or your local Micromass representative.

Section 2

Safety Notices

IsoPrime-EA User Manual

Warranty

The information contained within this document is subject to change without notice.

Micromass UK Ltd. makes no warranty of any kind with regard to this material, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose.

Micromass UK Ltd. shall not be liable for errors contained herein or for incidental damages in connection with the furnishing, performance, or use of this material.

Safety information

The IsoPrime mass spectrometer meets the following IEC (International Electrotechnical Commission) classifications.

Safety Class 1

Transient Overvoltage Category II

Pollution Degree 2

This unit has been designed and tested in accordance with recognised safety standards and designed for use indoors.

If the instrument is used in a manner not specified by the manufacturer, the protection provided by the instrument may be impaired.

Whenever the safety protection of the IsoPrime has been compromised, disconnect the instrument from all power sources and secure the unit against unintended operation.

Suitably qualified personnel only should perform maintenance procedures.

Substituting parts or performing any unauthorised modification to the instrument may result in a safety hazard.

Disconnect the mains supply before removing covers.

You must comply with all local and national requirements for electrical and mechanical safety.

Please contact the Customer Service Department at:

Micromass UK Ltd.
Floats road,
Wythenshawe,
Manchester,
M239LZ,
UK

Or your local Micromass representative should you require any further information.

Safety symbols

Warnings in the manual or on the instrument must be observed during all phases of service, repair, installation and operation of this instrument. Failure to comply with these precautions violates the safety standards of design and the intended use of the instrument.

Micromass UK Ltd. assumes no liability for the customer's failure to comply with these requirements.

The following safety notices and symbols are used in the manual or on the instrument.

WARNING

Warnings are given to highlight situations or conditions where failure to observe the instruction could result in injury or death to persons.

CAUTION

Cautions are given to highlight situations or conditions where failure to observe the instruction could result in damage to the equipment, associated equipment or process.

This symbol indicates that there are accompanying instructions which should be referred to for more information.

This symbol indicates where hazardous voltages may be present.

This symbol indicates a hot surface.

This symbol indicates a risk of corrosion.

Site requirements

The information contained within this section will allow the user to ensure that the laboratory is capable of supporting the operation of the IsoPrime mass spectrometer.

Temperature and humidity ranges

This equipment is designed for indoor use only. Operation within the recommended ranges will ensure optimum performance and lifetime.

After exposure to extremes of humidity or temperature, allow 15 minutes for it to return to the recommended ranges.

Temperature

Recommended temperature range: 20-27°C

Safe temperature range: 5-40°C

Humidity

Recommended humidity range: 50-60%

Safe humidity range:

Up to 31°C max. 80%

Then decreasing linearly to max. 50% at 40°C

Altitude

Altitude range: Up to 2000m

Cooling requirements

The IsoPrime is cooled by two cooling fans situated on the rear of the cubicle. Air is drawn in by the right-hand fan (viewed from the front) and expelled from the left-hand fan. Do not obstruct the flow of air around the cooling fans.

Caution: For proper cooling and general safety, always operate the instrument with cover panels properly installed and doors closed.

The rotary pump requires adequate ventilation. Consult the manufacturers instructions for details of the positioning requirements of the rotary pump.

Venting toxic or noxious gasses

The IsoPrime system has two points at which gas may be vented into the atmosphere. The rotary pump exhaust and the reference gas box.

All gas which enters the mass spectrometer will leave via the rotary pump exhaust. The exhaust ports of the rotary pumps are fitted with oil mist filters, however you may wish to connect to an exhaust line (15mm internal diameter) leading to a suitable exhaust point. Consult the rotary pump manufacturers manual for details of exhaust requirements.

The safe exhausting of these fumes should be given careful consideration when working with hazardous materials, for example SO₂.

IsoPrime-EA User Manual

The reference gas box freely vents both the carrier gas (Helium) and the reference gas in use, into the atmosphere.

Caution: If a reference gas injector is to be used for hazardous gasses the user should be aware that the gas is exhausted into the atmosphere both within the reference gas injection box and also from the rotary pump exhaust. It is essential that suitable extraction be installed so that the gas concentration in laboratory air complies with the local Health and Safety standards.

Benchtop requirements

The IsoPrime is a bench top instrument and may be placed on normal laboratory benches. The bench must be of a construction adequate to support the weight of the IsoPrime and associated prep systems. The bench should also be free of any vibration or movement that may impair the performance of the IsoPrime.

The IsoPrime (including reference gas injector box) has overall dimensions of:

Width 795mm

Depth 585mm

Height 535mm.

The minimum space requirements for the IsoPrime when placed on a bench are detailed in the drawing below. In addition to the clearance indicated there must be a 50mm diameter hole to allow the foreline to pass through or behind the bench. The IsoPrime is supplied with 2m of flexible tubing to connect to the rotary pump, which should be placed on the floor beneath the instrument.

IsoPrime-EA User Manual

The IsoPrime preparation systems require additional bench space as indicated in the following diagram. The preparation systems are normally located on the right hand side of the IsoPrime, and the computer system to the left. Under certain circumstances this positioning may be altered, please contact the factory for advice on where this is possible.

The GC interface is fitted to a freestanding bench and customers may wish to order a freestanding bench for the IsoPrime when ordering a GC interface.

The clearance heights marked on the drawing are for guidance only, shelves or overhanging obstructions will limit access to the instrument and may interfere with cooling.

Allow 100mm between and behind instruments to allow for proper ventilation and access for connections.

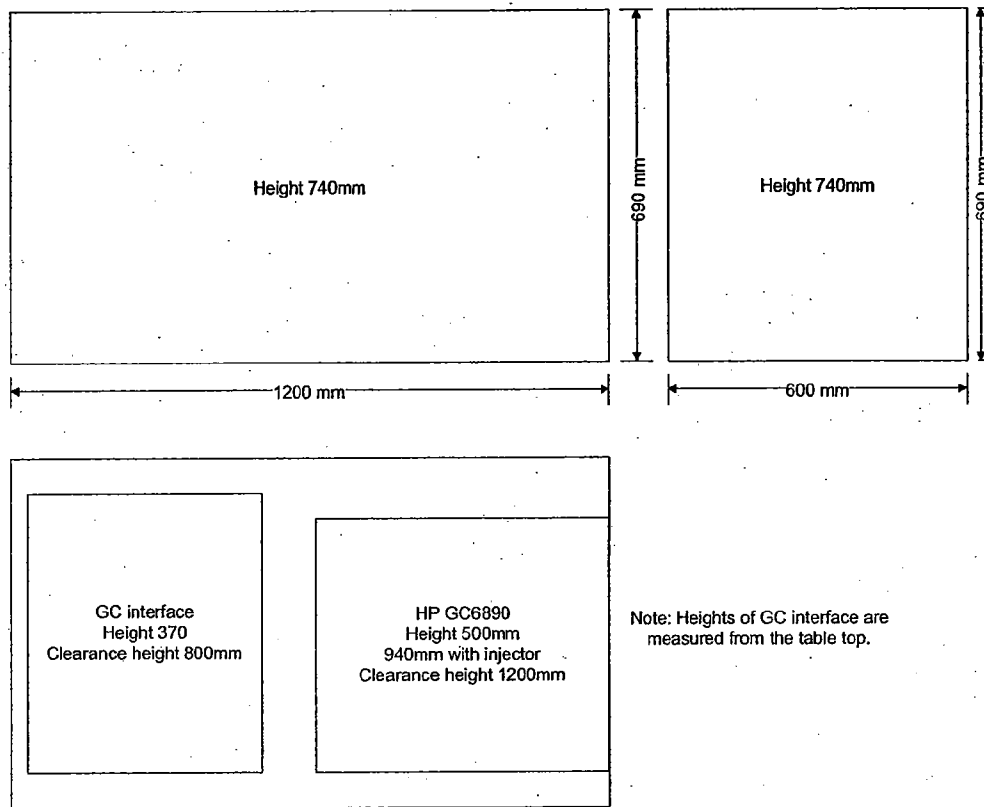

The approximate weights of individual units of the instrument are shown below:

| | |
|-------------------------------------|-------|
| Micromass IsoPrime cubicle | 82kg |
| Permanent magnet | 21kg |
| Electromagnet | 45kg |
| Computer | 55kg |
| Rotary pump | 23kg |
| Micromass GC interface | 130kg |
| Micromass µG interface | 43kg |
| Micromass EA interface | 130kg |
| Micromass Trace gas preconcentrator | 33kg |
| 600mm wide table | 22kg |
| 1200mm wide table | 33kg |

Freestanding requirements

The plan below shows the table sizes available for free standing placement of the IsoPrime and its interfaces. The smaller of the two tables will take the μ gas interface and the Trace gas preconcentrator. The larger table may be used for IsoPrime /reference gas box, elemental analyser or computer and printer. The GC interface is fitted to the larger of the two tables as standard and is shown in the drawing below.

Please allow clear floor space for at least 1 metre surrounding the instrument for maintenance access. The floor must be flat and free from vibration and have sufficient load bearing capacity.

Electrical requirements

The mass spectrometer and preparation systems may each require one or more connections to the mains supply, which should meet the following requirements:

Grounding

A proper earth ground is required for the safe operation of this equipment.

To protect users, the metal cubicle and analyser are grounded through the three-conductor power lead in accordance with the requirements of the IEC.

Earth grounding of the instrument is provided through the three-conductor power lead. When connected to a properly grounded receptacle, the instrument is also grounded and minimises shock hazard. A properly grounded receptacle is one that is connected to a suitable earth ground. Proper grounding should be verified.

Line voltage

Preparation systems require a 230V AC, 50-60Hz, single phase supply.

The IsoPrime mass spectrometer and rotary pump require a 110/230V AC, 50-60Hz single phase supply.

One terminal (the neutral) **must** be at earth (ground) potential. This is to ensure that the voltage on all conductors with respect to ground does not rise to an unsafe voltage.

Each circuit is supplied with one or more suitable mains supply cables. Connectors for attaching these cables to the local supply should be provided by the user.

Each circuit is supplied with a 2m cable to attach to the site mains supply. The cables supplied are terminated with a 10A IEC320/C13 cold condition free socket at one end and a UK mains 13A BS1363A plug at the other end. Customers requiring alternative terminations are advised to supply their own leads terminated with a 10A IEC320/C13 cold condition free socket.

Note: The elemental analyser mains cable is supplied with a 2m cable terminated with a UK mains 13A BS1363A plug at one end and an IEC320/C19 16amp connector at the other.

The individual current requirements of the mass spectrometer and preparation systems are shown in the table below. Some circuits are susceptible to large voltage transients. These should be protected by a suitable transient suppressor if the local supply is of poor quality. Some sites may also wish to protect some (the pumping circuits, for example) or all circuits from power failure with an un-interruptable power supply unit. Once again this depends on the quality of the local supply. If you need further advice on your local supply please contact your local Micromass sales and service organisation.

Users should ensure that the provision of the mains supplies described in this document is in accordance with any local regulations.

IsoPrime-EA User Manual

| System | Circuit | Source | Max. current @ 110V 60Hz | Max. current @ 230V 50Hz | Max. Fuse Rating | Approx. Heat Output | Transient Sensitive |
|----------------|-------------------------|--------|-----------------------------------|-----------------------------------|------------------------|---------------------------|------------------------|
| IsoPrime | Mass spectrometer | Mains | 7.2A | 3.4A | 10AT | 600W | Yes |
| IsoPrime | Rotary pump | Mains | 4.4A | 2.4A | 10AT | 300W | No |
| Data system | Computer + printer | Mains | N/A | 3A | 10AT | 500W | Yes |
| GC interface | Gas Chromatograph | Mains | N/A | 13A | 13AT | 2950W | No |
| GC interface | Interface (Furnace) | Mains | N/A | 3A | 3AT | 300W | No |
| µgas interface | Interface + autosampler | Mains | N/A | 1.2A | 3AT | 130W | Yes |
| EA | Elemental analyser | Mains | N/A | 6A | 13AT | 200W | No |
| Trace gas | Trace gas | Mains | N/A | 2A | 3.15AT | 725W | No |

Note: Each line in the above table represents an individual mains connection and uses an individual mains lead.

Note: mains supply voltage fluctuations should not exceed $\pm 10\%$ of the nominal voltage.

Special gasses

Compressed air

The Micromass IsoPrime requires no compressed air but each of its prep systems requires a regulated compressed air supply of 60 psi. If a compressed air line is not available, a compressor must be supplied.

The air supply should be oil, water and particulate free.

The air-line connections on the reference gas boxes and prep systems are 6 mm (OD) push-fit.

Gas requirements

The IsoPrime mass spectrometer is sensitive to contamination of supply gasses. The presence of any hydrocarbon, water or particulates will have a significant effect upon instrument performance and reliability.

The table below lists the minimum acceptable purity of gasses for use with the IsoPrime.

Not all prep systems require all gasses

| Gas | Purity | O ₂ content | H ₂ O content | Required for |
|-----------------|-----------------------------|------------------------|--------------------------|--------------|
| Helium | 99.999% | | < 1 v.p.m. | All systems |
| Oxygen | 99.998% | | | EA, GC(N) |
| Hydrogen | 99.999% | | < 2 v.p.m. | GC |
| Dry Air | Zero grade (best available) | | < 2 v.p.m. | GC |
| Carbon Dioxide | 99.995% | | < 4 v.p.m. | Ref gas |
| Nitrogen | 99.999% | < 1 v.p.m. | < 1 v.p.m. | Ref gas |
| Nitrous Oxide | 99.9% | < 1 v.p.m. | < 4 v.p.m. | Ref gas |
| Sulphur dioxide | 99.9% | | | Ref gas |

Warning: Compressed gas cylinders should be securely fastened to an immovable structure or permanent wall. Compressed gasses should be stored and handled in accordance with relevant safety codes.

Warning: To avoid possible eye injury, wear eye protection when using compressed gas.

Clean, two stage regulators must be fitted on the gas supplies. These should have stainless steel diaphragms. The second stage regulator must be capable of delivery pressures up to 6 Bar at the instrument.

The cylinder regulators or intermediate supply pipework should be fitted with connectors for 1/8" OD stainless steel capillary.

A supply of 1/8" OD stainless steel capillary should be available for connection of the instrument. Tubing should be of chromatography grade and free from oil or other contaminants. The lengths required will be determined by the location of the cylinders (or intermediate pipework) terminations and the intended placement of the instrument.

Note: For the reference gas pipework it is advisable to locate the cylinders as close to the instrument as possible. This reduces the possible sources of contamination of the reference gas and minimises the required purge time.

Should the cylinders be located some distance from the instrument, consideration should be given to the use of larger diameter tubing to reduce pressure drop across the supply pipe.

Lifting requirements

The components that comprise your IsoPrime instrument may be of considerable weight and may therefore pose a safety hazard when lifting, lowering or moving them.

IsoPrime-EA User Manual

UK health and safety guidelines (Manual Handling Operations Regulations 1992) require that all lifting/lowering operations are carried out by trained personnel and are planned before commencement.

As a general guide, before undertaking any lifting, lowering or moving operation:

- Assess the risk of injury
- Take action to eliminate risk

If some risk still exists:

- Plan the operation in advance and in conjunction with our engineer when he/she arrives on site.
- Use trained personnel where necessary.
- Adhere to appropriate country and/or company regulations.

Warning: Persons with a medical condition, for example a back injury, which prevents them from handling heavy loads should not attempt to lift the heavy components of the instrument. Micromass accepts no responsibility for any injuries or damage sustained while lifting the instrument.

Micromass personnel are not permitted to manually lift the instrument without suitable assistance from local site personnel.

The following information is provided to aid in planning lifting/lowering operations.

IsoPrime cubicle

The IsoPrime cubicle may weigh up to 82kg when fitted with optional equipment.

Suitably trained personnel will be required to raise or lower the cubicle, either manually or with the use of lifting equipment.

The cubicle lid must be removed before lifting (Open the lid to the vertical position and lift the hinges from their sockets), This brings the total weight to 77kg.

The UK health and safety guidelines recommend that a minimum of four trained and physically suitable personnel are required to lift a unit of this weight from the packing case to the bench. The personnel should be positioned for equal distribution of the load.

All other lifting operations should be assessed before commencement.

Lifting points for manual lifting

The cubicle should be lifted by four people positioned as shown in the diagram below.

Caution: Under no circumstances should the instrument be lifted by the doors, foreline-connection or lid. Hands should be placed underneath the instrument and support from the bottom.

Lifting points for mechanical lifting

The cubicle lid should be removed before slinging the instrument (Open the lid to the vertical position and lift the hinges from their sockets).

The sling should be run under the lip of the cubicle base-plate and in front of the cubicle feet as shown in the diagram below.

Care should be taken to stop the heavy end of the instrument from twisting in the sling.

Permanent magnet

The permanent magnet weighs 21kg. Lifting the permanent magnet from the packing case to the bench has been assessed as being within the safe lifting capability of two, trained, people.

Lifting the permanent magnet from the bench to the mounting position, has been assessed as being within the safe lifting capability of a single, trained, person.

All other lifting operations should be assessed before commencement.

Electromagnet

The electromagnet weighs 45kg. Suitably trained personnel will be required to raise or lower the magnet, either manually or with the use of lifting equipment.

The UK health and safety guidelines recommend that a minimum of three trained and physically suitable personnel are required to lift a unit of this weight from the packing case to the bench, or from the bench to the mounting position.

Personnel should be positioned for equal distribution of the load.

A lifting cradle is supplied with the instrument for manual or mechanical lifting and must be used for safe handling of the electromagnet.

Computer

The computer system is composed of a number of individual components. Each component is normally within the safe lifting capability of a single trained person.

The manufacturers documentation should be checked for specific handling recommendations before lifting.

Rotary pump

The RV3 rotary pump weighs 23kg.

The manufacturers documentation should be checked for specific handling recommendations before lifting.

GC-Interface

The GC interface is mounted on a wheeled table. Under normal circumstances lifting should not be required. If lifting is required then an assessment of the operation must be performed before proceeding.

Caution: The GC is not fixed to the table. Any lifting operation must secure the GC from movement.

µgas interface

The µgas interface is composed of a number of individual, connected, units. The interface should never be lifted as an assembly as the individual components are not tied together.

The individual components and their weights are given in the table below.

| Component | Weight /kg |
|---|------------|
| Oven housing | 11 |
| Sample tray (including racks and tubes) | 4.5 |
| Gilson autosampler | 15 |
| Gilson support | 2.5 |
| Oven/gas control unit | 10 |

Lifting the individual components from the packing case to the bench, and from the bench to the mounting position, has been assessed as being within the safe lifting capability of a single, trained, person.

All other lifting operations should be assessed before commencement.

EA interface

The elemental analyser weighs 130kg and the manufacturers guidelines for lifting and moving should be followed. See the manufacturers documentation for specific handling recommendations.

The EA diluter is within the safe lifting capability of a single, trained, person.

All other lifting operations should be assessed before commencement.

Trace gas preconcentrator

The Trace gas preconcentrator weighs 33kg.

The UK health and safety guidelines recommend that a minimum of two trained and physically suitable personnel are required to lift a unit of this weight from ankle height to the bench. The personnel should be positioned for equal distribution of the load.

The Trace gas preconcentrator should be lifted by two people positioned as shown in the diagram below.

Caution: Under no circumstances should the instrument be lifted by the rear of the instrument where indicated on the diagram or by the sample tube support.

Technical specification

Mass range

1-70 AMU (using electromagnet).

Resolution

The analyser is set to a working resolution of 100 (10% valley definition).

H3+ Contribution (SMOW)

The H3+ contribution is <10 PPM/nA.

Analyser continuous flow specifications

Performed using a reference gas box and continuous flow interface.

Applies to all continuous flow modules.

Reference gas precision ^{13}C

$\leq 0.1\text{‰}$ (SD 1 σ ; on the fit of 10 consecutive pulses of 5nA height).

Reference gas precision ^{15}N

$\leq 0.1\text{‰}$ (SD 1 σ ; on the fit of 10 consecutive pulses of 5nA height).

Reference gas linearity ^{13}C

$\leq 0.3\text{‰}$ (SD 1 σ ; on the fit of 10 pulses varying in height between 1-10nA).

Reference gas linearity ^{15}N

$\leq 0.3\text{‰}$ (SD 1 σ ; on the fit of 10 pulses varying in height between 1-10nA).

Introduction

This section of the manual is aimed at those users who are new to isotope ratio mass spectrometers (IRMS) or are unfamiliar with some of the basic concepts of these instruments. This section only touches the surface of the material it could cover. However we feel that it is sufficient in depth to enable the new user to move on to use the instrument with confidence and understanding. Most experienced users will probably ignore this section, however the 'Calculations and Corrections' pages contain definitions of formulae for calculations and corrections generally used and thus may be of interest as a reference section.

This is a generalised section and is used in all the user manuals, so please ignore any parts which are not relevant to the system.

Basic mass spectrometry concepts

Mass Selection

If an ion of mass M and charge Z is accelerated in a potential V and injected into a uniform magnetic field B then the ion experiences a force and moves in a circular orbit of radius R . The motion is defined by;

$$\frac{M}{Z} = \frac{B^2 R^2}{2V} \quad (1)$$

for singly-charged ions the radius is determined by the choice of magnetic and electric field. The combination of fields selects ions of particular mass and forms a mass filter. This principle is the basis of all magnetic-sector mass spectrometers and equation (1) is frequently termed the mass spectrometer equation.

Mass Spectrometers

To analyse a sample gas its molecules must be ionised, formed into a beam, accelerated by an electric field, deflected in a magnetic field, and finally detected. These five processes take place in the analyser of a mass spectrometer, which consists of three separate sections: the source, flight tube, and collector. Ionisation, beam formation and acceleration all occur in the source, magnetic deflection takes place in the flight tube and detection takes place in the collector.

The ionisation is commonly achieved by passing a beam of electrons through the gas sample. Collision or close approach of an electron and sample molecule can cause one or more electrons either to adhere to the molecule and form a negative ion, or to detach from the molecule and leave a positive ion. Except in special cases, it is the singly-charged positive ions (molecules that have lost one electron) which are used in mass analysis. These positive ions are accelerated and formed into a well-defined beam by raising the ionisation chamber to a positive potential and accelerating the ions out through a slit towards a second defining slit at ground potential. The two slits are known as the source and alpha slit respectively.

The flight tube forms an arc of a circle and passes between the poles of a magnet. As the ion beam travels down the tube, it is separated into beams of different radii corresponding to different masses. A particular radius, and hence mass, is selected by a slit at either end of the flight tube; the alpha slit in the source and the resolving slit in the collector.

In the collector, ions of the chosen mass are transmitted through a resolving slit and detected by a Faraday cup. The ion current from the cup is proportional to the number of incident ions and hence to the partial pressure of the corresponding isotopic molecular species in the sample gas. Multiple slits and Faraday cups are frequently used to obtain simultaneous detection of different masses. This method is used in isotope ratio instruments to measure a major beam, due to the most abundant isotopic species of a molecule, and minor beams from the less abundant species.

Mass Separation Diagram

Analytical and Isotope Ratio Analysers

The most pronounced difference between analytical and isotope ratio instruments lies in the peak shape observed by scanning the magnetic or electric fields. In analytical work a mass range is scanned to obtain a spectrum of mass peaks which are characteristic of chemical composition. In isotope ratio work the chemical composition of the sample is known and the fields are held constant so that the variations of isotopes in one chemical species may be measured with high precision. Thus an analytical instrument requires a very narrow peak to distinguish closely spaced masses, whereas a very broad peak is required for high stability in the amplitude measurements of isotope ratio instruments.

Peak Shape

Peak shape is defined by the source and resolving slits because the analyser is constructed such that the image of the source slit is focused at the resolving slit. (The alpha slit merely eliminates unwanted ions.)

For a resolving slit (at the collector) much narrower than the source slit, a triangular peak shape would be observed as the image of the source slit was swept across the resolving slit (see Narrow Collector Slit figure below). Thus the source slit determines the minimum peak width.

For a resolving slit much wider than the source slit, the image of the source slit would be wholly contained within the resolving slit, and there would be a broad range of electric and magnetic fields over which the image of the same mass could be observed. Although the slopes of the triangular peak would remain, they would be separated by a large mass range over which the signal did not change and a broad flat-topped peak would be observed (see Wide Collector Slit figure below). Thus the resolving slit determines the width of a flat-topped peak, which is limited simply by the encroachment of the adjacent mass peaks.

A narrow source and resolving slit suit analytical measurements, but a narrow source and broad resolving slit best accomplish isotope ratio measurements.

Narrow Collector Slit

Wide Collector Slit

Dispersion

The mass dispersion determines the separation between adjacent mass peaks.

For an analyser of radius r , source slit-to-magnet exit distance x_s and resolving slit-to-magnet exit distance x_r , the mass dispersion measured perpendicular to the ion trajectory is expressed as:-

$$D = \Delta r \left| 1 + \sqrt{\frac{(r^2 + x_r^2)}{(r^2 + x_s^2)}} \right| \quad (2)$$

However, differentiating the mass spectrometer equation ("Mass Selection" above, equation (1) gives:-

$$\frac{\Delta M}{M} = \frac{2\Delta r}{r} \quad (3)$$

and therefore the mass dispersion may be expressed as:-

$$D = \frac{r\Delta M}{2M} \left| 1 + \sqrt{\frac{(r^2 + x_r^2)}{(r^2 + x_s^2)}} \right| \quad (4)$$

In a symmetrical analyser where $x_s = x_r$, the mass dispersion reduces to:-

$$D = 2\Delta r = \frac{r\Delta M}{M} \quad \text{or} \quad D = \frac{r\Delta M}{M} \quad (5)$$

in isotope ratio instruments where peaks are separated by one mass unit. It is clearly seen that dispersion is specified by the radius of a symmetrical instrument and this is frequently quoted as the dispersion itself.

For an asymmetrical analyser, the dispersion is frequently compared to an effective radius

$$r_{\text{eff}} = \frac{r}{2} \left| 1 + \sqrt{\frac{(r^2 + x_r^2)}{(r^2 + x_s^2)}} \right| \quad (6)$$

which combines all the necessary geometric information.

Resolution

Two peaks are completely separated if (neglecting aberrations):

$$D > (W_s + W_r)$$

where W_s is the source slit width
and W_r is the resolving slit width

Mass resolution is defined as

$$R = \frac{M}{\Delta M}$$

from 5

$$R_{\max} = \frac{r_{\text{eff}}}{D} \quad (7)$$

which (from 6) is a maximum when $D = W_s + W_r$

$$\text{i.e. } R = \frac{r_{\text{eff}}}{W_s + W_r} \quad (8)$$

The resolving power of a mass spectrometer is the highest mass number at which peaks of adjacent molecular weight and equal heights have a valley between them of 10% of the peak height. This is known as the 10% valley definition.

Valley Resolution

As an alternative 5% definition is identical to the 10% valley. In this case ΔM is defined as the width of the peak at the 5% height espoused as a proportion of the distance between adjacent masses.

5% Peak Height Resolution

The separation between the peaks is determined by the image size, ions extracted from the source on the wrong trajectory and by aberrations in the optics.

In principle the maximum resolution is directly calculable from the radius and slit width equation (8).

However, the design of the high sensitivity source used in Isotope machines results in a high intensity image which is narrower than the source defining slit and so increases the actual available resolution of the instrument.

Vacuum System

Why Do We Want a Vacuum?

In mass spectrometry we are particularly interested in vacuums for two reasons:-

1. Ion scattering:- If the ions collide with any residual gas molecules their trajectory will be modified resulting in peak broadening.
2. Contamination:- Residual gases in the ionising chamber are also ionised together with the sample material giving rise to an instrument background.

How Do We Measure a Vacuum?

Gases are composed of small particles which are in constant motion. As these particles move around in space they collide with other objects and exert a force. If we can take a unit of area and measure the number and intensity of particle impacts then the resultant is a pressure measurement.

The pressure per unit area P is

$$P = \frac{1}{3} nmv^2$$

where

$$v = \left(\frac{3kT}{m} \right)^{\frac{1}{2}}$$

m is the mass of the molecule,

n the number of molecules in unit volume.

v is the root mean square of all the possible molecular velocities.

k is Boltzmann's constant (1.38×10^{-23}) Joule T^{-1}

and T the temperature of the gas in degrees Kelvin.

Units of Pressure

Atmospheric pressure is equivalent to

| | |
|---------|----------------------|
| 14.7 | lbs per sq inch |
| 760 | mm of Hg |
| 760 | Torr |
| 760000 | millitorr or microns |
| 101325 | Pascal |
| 1.01325 | Bar |
| 1013.25 | millibar |

Common terms for pressure regimes are

| | |
|--------------|---------------------------------|
| Rough vacuum | 10^3 to 10^{-3} millibar |
| High vacuum | 10^{-3} to 10^{-8} millibar |
| UHV | $< 10^{-8}$ millibar |

Gas Flow

The process of evacuation involves the removal of gas from a vacuum vessel. The rate of removal (i.e. the gas flow) determines the rate at which the pressure decreases. It is therefore important to understand viscous and molecular flow regimes.

Viscous Flow

In general gas molecules occupying a space at pressures of greater than 10^{-2} millibar act very much as a fluid. In this viscous flow range the molecules are constantly bumping into each other and are so closely packed together that as the vacuum pump moves some of them out of the chamber others rush to fill that empty space. In viscous flow ranges molecular movement is predictable and smaller diameter hoses and tubes can be used for rough pumping. Viscous flow allows great quantities of molecules to be moved per unit time from one place to another.

Molecular Flow

At lower pressures molecules are so far apart that they no longer exert any influence on each other and motion is strictly random. Depending on pressure a gas molecule may move mm, cm, meters, or even kilometres before it strikes another molecule. This means molecular movement cannot be depended on to push or start a flow pattern. This is why we need to have such large diameters on high vacuum pumping systems, as then we increase the probability that one of these randomly moving molecules will move into the pump.

The difference between the flow regimes does not depend solely on pressure but also on the dimensions of the vacuum container, pipes, etc. It basically depends on the mean free path of the gas molecules.

Pumps

The purpose of a pump is to provide a means for removing gas. Its pumping speed S is rated in litres per second. Most practical pumps operate continuously so that if a constant flow of gas Q is introduced into the pump then a steady state is set up with an associated constant pressure within the pump. The pumping SPEED is defined as

$$S = \frac{Q}{P}$$

and is clearly an indication of pumping ability.

Air is easily removed at high pressures but after a short while very little gas remains so that pumping speed does not indicate how many molecules are being removing from the system. The amount of gas present in the system is determined by multiplying the pressure (in torr) by the volume (in litres) which tells us the number of molecules in the system or the gas LOAD. Apart from back streaming of pump fluids and influx from real leaks, there are four main sources of gas load in a high vacuum system: (1) desorption of absorbed gases, (2) volatilisation, (3) diffusion of gases from inside solids and (4) gas permeation.

In vacuum systems we are interested to know how much work has to be done to transfer a mass of gas from one place to another.

The Rotary Vane Pump

The rotary vane pump removes gases by compressing them to a point slightly above atmospheric pressure by means of an offset rotor with spring loaded vanes. It then expels the gas to the outside world, approximately 99.999% of the air being removed. It is used to produce rough or foreline pressures. The pump is immersed in an oil bath and the oil is purified to remove high vapour pressure contaminants. It serves to cool and lubricate the pump and provides the seal against atmospheric pressure. The pump motor may be directly coupled or belt driven. Most pumps have two stages to produce a better vacuum. As the film of oil makes the final seal the ultimate pressure achievable is partly determined by the vapour pressure of the oil. If the oil becomes too loaded with water or other impurities the pump's performance will be drastically reduced. Clean oil in the rotary pump is therefore very important. When operating at low pressures the rotary vane pump tends to back stream oil vapour to the roughing line which may even migrate to the vacuum chamber. This can be controlled by means of suitable precautions such as foreline traps in the pumping line.

Rotary Vane Pump

An oil-sealed mechanical pump includes a housing, or stator, an offset rotor with spring loaded vanes, an intake port and an exhaust port equipped with a discharge valve. They may also have a ballast valve. Direct drive pumps usually run at 1725 rpm. For a more detailed description please refer to the pump manufacturers manual.

The Turbo Molecular Pump

A Turbo Molecular pump (TMP) is essentially a high speed axial compressor. Gas is taken from the low vacuum side, compressed and exhausted to the vacuum foreline to be pumped away by the rotary pump.

If the TMP is turned off while open to the vacuum system, hydrocarbons from the foreline and motor bearing will diffuse through the rotor/stator interspaces to the high vacuum part of the pump. A vent valve which admits vent gas to the TMP is opened when the pumping system is turned off and the pump speed has dropped below 50% of the full rotational speed to prevent this back diffusion.

The TMP will only operate if the rotary pump is working. The TMP is self regulating and accelerates as the pressure drops.

Turbo Molecular Pump

For a more detailed description please refer to the pump manufacturers manual.

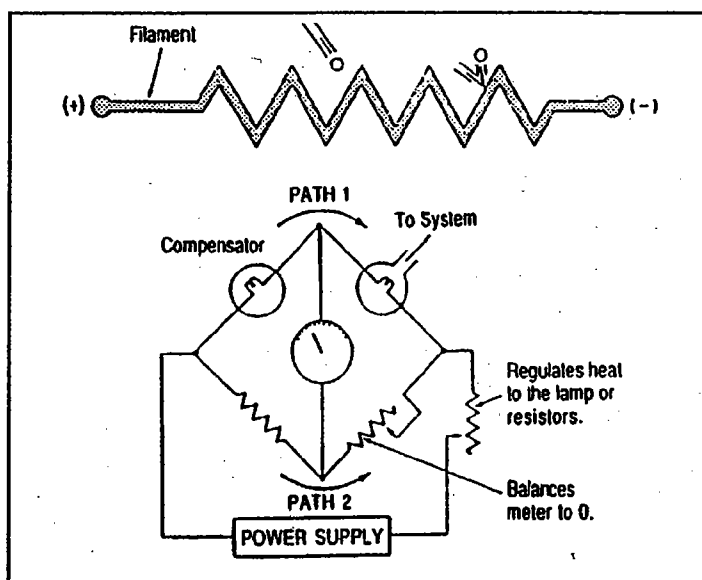

Pressure Gauges

Total Pressure Transducer

This consists of a stainless steel pressure chamber isolated by a stainless steel diaphragm which is resistant to corrosive materials. The inner face of the metal diaphragm has high gain strain gauges bonded to it. When the diaphragm is deflected resulting from a change in pressure in the vacuum system, the strain gauge output changes. This 1-6V output signal is proportional to system pressure and is monitored to give a measure of pressure in mBar.

The Pirani Gauge

This is very similar to the thermocouple gauge in operation in that it relies on gas molecules colliding with a filament conducting heat away. However in this case the filament resistance rather than the temperature is measured. The filament forms part of a bridge circuit. In the balanced bridge circuit the current flow through path one and two is equal and a meter placed at the centre as shown reads zero. When the filament changes resistance the balance is upset and a voltage difference is developed at the meter terminals and a current flows through it. This is calibrated in terms of pressure. The compensator is very similar to the filament and is held at a constant temperature and pressure. The Pirani gauge generally operates in the range 10^3 mBar to 10^{-3} mBar.

Pirani Gauge

The Ionisation Gauge

The ionisation gauge works on a very similar principle to an ion pump and is unique in that it can operate over 12 orders of magnitude from 10^{-2} mBar to 10^{-14} mBar. It is more commonly used over 6 orders of magnitude from 10^{-4} to 10^{-10} mBar and is expected to be within 30-50% of the correct pressure for high vacuum work.

It consists of a hot filament, a grid, an ion collector and a control unit to provide power, amplification and metering. Electrons from the hot filament are emitted and attracted towards the grid. However many electrons miss the grid wires and swing around it several times before striking it. Because of the large number of electrons emitted from the filament a fairly constant

IsoPrime-EA User Manual

electron cloud is formed about the grid. Many electrons collide with gas molecules ionising them and releasing more electrons. The positively ionised molecules are attracted towards the collector where they produce an ion current proportional to the number of gas molecules in the chamber and hence the pressure. To get meaningful pressure readings the sensitivity of the gauge must be known and the emission current well regulated.

The Ionisation Gauge

It should be noted that sensitivity varies with different gas species. Ion gauges are usually air calibrated and therefore most accurate when analysing nitrogen.

The ionisation gauge like any other has its limitation. Low energy X-rays are created when the electrons strike the grid which causes the releases of photo-electrons and hence a constant error signal. Above 10^{-10} mBar this is insignificant but at lower pressures, corrections must be made for this X-ray effect.

The Penning Gauge

The Penning Gauge operates on the principle that, at pressures below 100mBar, the ionisation current flowing between two electrodes varies with pressure. The interior of the head is open to the vacuum system and contains a rod anode surrounded by a cylindrical cathode. A magnetic field is maintained in the gauge by an external permanent magnet.

Simplified Penning Gauge Diagram

A DC voltage is applied between the anode and cathode which causes free electrons, which are accelerated from the cathode toward the anode. These electrons collide with any gas molecules present causing ionisation. The resulting electrons and positive ions are also accelerated by the electrostatic field causing further ionisation. The mean path length of each ion is extended as they follow a spiral path in the magnetic field. The net current flowing between the anode and cathode is then detected by the control unit and is a function of the pressure in the gauge head.

Notes:

- a) It should be noted that sensitivity varies with different gas species. Penning gauges are usually air calibrated and therefore most accurate when analysing nitrogen.
- b) Prolonged operation of the Penning gauge head above a pressure of 10^{-2} mBar is not recommended as permanent damage can be caused by sputtering.

The time taken for the gauge head to 'strike' (start reading the pressure) increases with decreasing pressure.

Sample Inlet Principles

Continuous Flow Operation

The Continuous Flow Inlet comprises of two vitreous silica capillaries which continuously carry Helium gas into the ion source of the mass spectrometer. These two capillaries draw Helium at two open splits, one fed from a reference gas injector system, the other from a sample preparation system (e.g. gas chromatograph, elemental analyser or μ gas injector).

At user defined times the reference gas injector pulses rectangular peaks of pure reference gas, (pre-calibrated against an international standard) into the ion source. The sample gases exiting from a gas chromatographic column are carried by a stream of Helium towards the sample open split, from here the sample gases also enter the ion source.

The areas under the sample and reference peaks are calculated, from which the difference in isotopic composition between the two is evaluated. This difference is expressed in delta notation, details of which can be found in the Calculation and Corrections section below.

Calculations and Corrections

Enrichment Delta, δ

Enrichment is the excess of any particular isotope species in the sample compared to the same isotopic species in the reference. The enrichment delta expresses this excess as a fraction of the particular isotopic species in the reference and is almost universally quoted in parts per thousand and written as ‰ or per mil. Thus the enrichment delta is;

$$\delta = \left(\frac{R_{sam} - R_{ref}}{R_{ref}} \times 1000 \right) \text{‰}$$

Where R_{sam} and R_{ref} are the sample and reference ratios of minor to major beam as measured on the isotope ratio instrument.

Enrichment delta notation can be used to express results for all species of gases measured.

Isotopic Abundance (Atom%)

This expresses the number of atoms of a particular isotope of an element in the sample as a fraction of the total number of atoms of that element present. It is usually expressed as a percentage and notated as Atom% or At%.

This notation is particularly popular amongst the biological users and for nitrogen measurement can be defined as:-

$$\text{Atom\%} = \frac{\text{number_of_}^{15}\text{N_atoms}}{(\text{number_of_}^{15}\text{N_atoms}) + (\text{number_of_}^{14}\text{N_atoms})}$$

Some users prefer to express their results as atom% excess (i.e. atom% enrichment in excess of the reference gas) which is defined as

Atom% excess = sample atom% - reference atom%

Internal Reproducibility

In a set of n measurements of a quantity x whose mean is x_{mean} there are two commonly used and related quantities for the precision.

Standard deviations of a measurement, σ

This is also referred to as the standard deviation and defines the precision of one individual measurement from the complete set of measurements. It is estimated from the data by

$$\sigma = \sqrt{\frac{\sum (x - x_{mean})^2}{(n-1)}}$$

Standard deviation of the mean, σ_{mean}

This is also referred to as the standard error and defines the precision of the average over the complete set of measurements. It is rigorously related to the standard deviation by

$$\sigma_{mean} = \frac{\sigma}{\sqrt{n}} = \sqrt{\frac{\sum (x - x_{mean})^2}{n(n-1)}}$$

The internal reproducibility of an instrument is defined as its standard error, where n is the number of values of delta produced by one set of sample/reference comparisons. For example a set of 6 pairs of sample/reference comparisons producing 10 values of delta would give

$$\sigma_{mean} = \sqrt{\frac{\sum (x - x_{mean})^2}{90}}$$

Instrument Corrections

In isotope ratio instruments there are three correction factors which may be of concern

A tail contribution from major to minor isotope peak.(abundance sensitivity correction)

A background gas peak at the minor isotope mass.

If the vacuum system is clean, background corrections also should be ignored, although software facilities are available to subtract background readings from all acquired data if required. If the sample has been prepared incorrectly, there may be problems due to contaminants at the masses of interest (e.g. CO peaks overlapping with nitrogen peaks in a dirty nitrogen sample). This type of interference may cause small errors in delta values. The peak jump facilities in the software are provided in order to assess the nature of possible contaminants.

Carbon Dioxide Corrections (Craig)

When analysing CO_2 different isotopic species of the same element can produce a contribution at certain masses and a correction must be made. For example the international CO_2 standard PDB has a contribution (approximately 6%) at mass 45 due to the ^{17}O isotope. Similarly, 0.2% of mass 46 is derived from isotopic species containing ^{13}C and ^{17}O but not ^{18}O . Masses higher than 46 have negligible abundance's.

For a triple collector instrument measuring a sample close to PDB, the correction formulae are

$$\delta^{13}C = 1.0676\delta(45/44) - 0.0338\delta^{18}O$$

and

$$\delta^{18}O = 1.0010\delta(46/44) - 0.0021\delta^{13}C$$

Nitrogen Corrections

When analysing nitrogen a problem can, at low enrichments, arise owing to trace nitrous oxide (NO) causing an interfering peak at mass 30. This, if not correctly taken into consideration, can adversely affect the resultant calculation of ^{15}N atom%.

To overcome this problem it is common to use a formula modified from the standard formulae when the enrichments are low (less than 5%). The two formulae commonly used are:

Standard formula for high enrichments

$$^{15}N_{atom\%} = \frac{R_{29} + 2R_{30}}{2(1 + R_{29} + R_{30})} \times 100 \quad (1)$$

modified formula for low enrichment

$$^{15}N_{atom\%} = \frac{R_{29}}{2 + R_{29}} \times 100 \quad (2)$$

where R_{29} = 29/28 mass ratio

and R_{30} = 30/28 mass ratio

Derivation of formula used

Given the probabilities of $^{15}N = \alpha$ and $^{14}N = 1 - \alpha$, then assuming the nitrogen sample is in equilibrium the N_2 probabilities can be expressed as:-

$$mass_{28}(\text{denoted } I_{28}) = (1 - \alpha)^2$$

$$mass_{29}(\text{denoted } I_{29}) = 2\alpha(1 - \alpha)$$

$$mass_{30}(\text{denoted } I_{30}) = \alpha^2$$

IsoPrime-EA User Manual

From The following 29/28 and 30/28 ratios can be expressed as:

$$R_{30} = \frac{\alpha^2}{(1-\alpha)^2} \quad \text{and} \quad R_{29} = \frac{2\alpha}{1-\alpha}$$

hence giving $R_{30} = \left(\frac{R_{29}}{2}\right)^2$ (3)

Atom% can be written as

$$\frac{2(^{15}\text{N}^{15}\text{N}) + (^{15}\text{N}^{14}\text{N})}{2(^{14}\text{N}^{14}\text{N}) + 2(^{14}\text{N}^{15}\text{N}) + 2(^{15}\text{N}^{15}\text{N})} \quad (4)$$

$$\text{Atom}\% = \frac{2I_{30} + I_{29}}{2I_{28} + 2I_{29} + 2I_{30}} \times 100 \quad (5)$$

Giving the standard high enrichment formulae (1)

$$\text{Atom}\% = \frac{R_{29} + 2R_{30}}{2(1 + R_{29} + R_{30})} \times 100 \quad (1)$$

Substituting (3) in (1)

$$\text{Atom}\% = \frac{2\left(\frac{R_{29}}{2}\right)^2 + R_{29}}{2\left(1 + R_{29} + \left(\frac{R_{29}}{2}\right)^2\right)} \times 100 \quad (6)$$

$$\text{Atom}\% = \frac{R_{29}^2 + 2R_{29}}{4\left(1 + R_{29} + \frac{R_{29}^2}{4}\right)} \times 100 \quad (7)$$

$$\text{Atom}\% = \frac{R_{29}(R_{29} + 2)}{(R_{29} + 2)(R_{29} + 2)} \times 100 \quad (8)$$

which gives the modified low enrichment formulae

$$\text{Atom}\% = \frac{R_{29}}{2 + R_{29}} \times 100 \quad (9)$$

Both formulae (1) and (2) have limitations:-

formula (1) although accurate at high enrichments can cause errors at low enrichments due to the presence of Nitrous Oxide.

formula (2) overcomes the NO constitution problem at low enrichments by substitution of R_{29} ratios, however it relies on equilibrium of sample nitrogen, thus causing possible errors at high enrichments.

The normal method is to switch between the two formulae at a particular enrichment. The level of enrichment that is decided is dependant on the sample nitrogen. i.e. how well it is equilibrated and its NO concentration.

Other Analysis Considerations

Note: The following sections are provided to allow users to fully understand the data reduction algorithms used in the program. Users may wish to skip this section on first reading.

Sequence of data reduction (General case)

The following calculations are performed where necessary for any gas:

Convert the reference gas deltas to the standard format for further calculation.

For example if CO₂ is being analysed and the reference deltas are input as delta(13) and delta(18), it is necessary to convert these values to delta(45) and delta(46) for further use. This is done automatically if required using the Craig formulae.

Convert the sample delta, measured with respect to the laboratory standard, to the delta w.r.t. the international standard.

This is done using the following formula:

$$\delta(\text{sam w.r.t. international}) = \delta(\text{sample}) + \delta(\text{ref w.r.t. international}) + \frac{\delta(\text{sample}) * \delta(\text{ref w.r.t. international})}{1000}$$

Convert the observed delta values of a gas comprising more than one element to the delta values for the pure element.

The most familiar example is probably the Craig correction for CO₂ mentioned above. The other common case is for sulphur analyses using the 64 and 66 peaks of SO₂. To allow these calculations to be undertaken in the general case a matrix is set up using constants from the parameter file (only accessible at supervisor level) such that:

$$\delta 1(\text{corrected}) = C1 * \delta 1 - C2 * \delta 2(\text{corrected})$$

$$\text{and } \delta 2(\text{corrected}) = C3 * \delta 2 - C4 * \delta 1(\text{corrected})$$

This format has been chosen to closely represent the original Craig formulae. A little thought shows :

| | CO ₂ | CO | SO ₂ | N ₂ | HD |
|----|-----------------|--------|-----------------|----------------|----|
| C1 | 1.0676 | 1.0378 | 1.09 | 1 | 1 |
| C2 | 0.0338 | 0.0169 | 0 | 0 | 0 |
| C3 | 1.0010 | 1.0010 | 0 | 1 | 0 |
| C4 | 0.0021 | 0.0021 | 0 | 0 | 0 |

This general approach allows most gas species to be analysed by determining the values of the four constants. It also allows for non standard collector arrangements to be utilised by careful choice of constants.

A number of preparation systems rely on equilibrium states being reached, rather than reactions proceeding to completion. Examples include the carbonate reaction with acid, the carbon dioxide equilibration over water for oxygen analysis and the hydrogen equilibration over water for hydrogen analysis. The equilibration can be treated in a general way as

$$\delta(\text{true}) = \frac{(\delta(\text{measured}) - 1000 * (E - 1))}{T(\text{standard})} + K * (T(\text{reaction}) - E)$$

IsoPrime-EA User Manual

By specifying E as 1 and K as 0 this formula can be applied to any delta as it will not change the result. **THIS IS THE DEFAULT AND SHOULD NOT BE CHANGED UNLESS A CORRECTION IS REQUIRED.**

For the determination of the oxygen isotope ratio in waters by equilibrium the constants are :

$$E = 1.04115 \text{ and } K = 0.17 \text{ (approx)}$$

whilst in the carbonate reaction using phosphoric acid:

$$E = 1.01025 \text{ and } K = 0.04.$$

The value of T(standard) is normally 25°C. These constants are input in the gas parameter files.

A Simple Example for Carbon Dioxide

If the delta 13 and delta 18 of the reference gas are input these are converted to delta 45 and delta 46 using:

$$\delta 45 = (\delta 13 + (C2 * \delta 18)) / C1$$

$$\delta 46 = (\delta 18 + (C4 * \delta 13)) / C3$$

The sample deltas measured with respect to the lab gas are then modified to be w.r.t. the international standard using the formula given in (2) above.

We can then use the Craig constants again to calculate the delta 13 and 18 of the sample gas relative to the international standard by:

$$\delta 13 = ((C1 * \delta 45) - (C2 * C3 * \delta 46)) / (1 - C2 * C4)$$

$$\text{and } \delta 18 = ((C3 * \delta 46) - (C1 * C4 * \delta 45)) / (1 - C2 * C4)$$

If the corrections are done in any other order the Craig constants (which apply for PDB only) would have to be re-calculated, a point often missed.

Calculations specific to Carbon Dioxide

Santrock and Hayes

These authors have suggested an alternative algorithm for converting delta 45 and 46 to delta 13 and 18 which has yet (at the time of writing) not achieved international recognition. They start from the general formula relating the oxygen 17 to oxygen 18 ratios of:

$$^{17}\text{R} = K(^{18}\text{R})^\alpha$$

The derivation of Craig which is used by most users assumes that the constant (α) has the value of 0.5 and permits an exact derivation of the corresponding equations to determine delta 13 and 18. In the general case considered by the above authors an iteration approach is required. The values of the constants K and α are not well determined. At the time of writing the "best" values appear to be:

$$\alpha = 0.516 \text{ and}$$

$$K = 0.0099235.$$

Two other constants are required for this analysis, namely the carbon 13 to carbon 12 ratio and the oxygen 18 to oxygen 16 ratio in the international standard PDB. (The oxygen 17 ratios are obviously determined in the calculation using the above formula). These values are:

$$^{13}\text{R}_{\text{PDB}} = 0.0112372$$

$$^{18}\text{R}_{\text{PDB}} = 0.002079$$

IsoPrime-EA User Manual

If the Santrock method is required the user is responsible for determining that the constants employed are correct, otherwise the final reported data will be in error.

These constants can be inserted in the parameter file, accessible only at supervisor level. For further discussion of this technique the reader is referred to the original papers:

Santrock, Studley and Hayes: Anal. Chem 57 1444-8 (1985) and

Bakke, Beaty and Hayes - Paper presented at GSA 1991.

Finally it should be noted that (obviously for consistency) if this approach is to be used the reference gas deltas should be converted to a delta 45 and delta 46 value by the same technique off-line, and these values loaded into the appropriate parameter file. If the delta 13 and 18 values are input the Craig method is automatically employed to do this calculation.

SMOW

Since two international standards for oxygen isotopes exist, PDB and SMOW, it is necessary to be able to report the analyses relative to both standards. The formula used is:

$$\delta 18(\text{SMOW}) = \delta 18 * E + 1000 * (E-1)$$

Where the equilibrium constant E has the value 1.03086.

Atom % Carbon

Once the enrichment of the sample has been determined relative to a reference, it is straightforward to calculate the carbon atom % composition of this sample, using the known composition of the reference. The three constants used in this calculation (13R, 18R and 17R) specified in the parameter file supplied (accessible at supervisor level only) refer to the international standard PDB. If an alternative standard is required it is left to the user to determine the required constant values.

Calculations Specific to Nitrogen

Atom % Nitrogen

Once the enrichment of the sample has been determined relative to a reference, it is straightforward to calculate the nitrogen atom % composition of this sample, using the known composition of the reference. The single constant used in this calculation (¹⁵R) specified in the parameter file supplied (accessible at supervisor level only) refers to the international standard of the nitrogen in the air. If an alternative standard is required it is left to the user to determine the required constant value.

Enriched Nitrogen Analysis

It is sometimes necessary to determine the nitrogen isotopic composition of a sample which is close to natural but where the ^{15,15}N₂ is not in thermodynamic equilibrium with the ^{14,14}N₂ and ^{15,14}N₂. In this case the simple formulae given above may not be used and the analysis must take account of the 28, 29 and mass 30 signals. A problem is often encountered with trying to use the mass 30 signal in that the recorded signal is due not only to a contribution of nitrogen (which is the signal of interest), but also a large contribution from NO is often seen, especially if even a minute trace of air is present in the samples being analysed.

To permit this analysis to be undertaken the following approach is used:

IsoPrime-EA User Manual

- The delta 29 and delta 30 of the sample is calculated in the normal manner.
- From the calculated atom % of the reference gas (obtained from the input atom percent of the international standard and the reference gas delta value) the expected 30 AMU signal is calculated and the difference between this value and the observed is assumed to be the unwanted contribution from NO. This calculation assumes that the mass 30 of the reference gas is in thermodynamic equilibrium (otherwise no method exists to determine the NO signal in the general case).
- The assumption is also made that this contribution is also present in the sample gas (i.e. that they have both similar oxygen impurities or that the major source of oxygen is elsewhere, e.g. from the filament) and the mass 30 AMU signal modified accordingly. The correction used is weighed so that at natural abundance the full correction is used whilst at 100% enrichment the correction falls to zero.
- This corrected 30 signal is then the value used in the subsequent atom % calculation.

If it is felt this approach is inappropriate for the samples being analysed it is left to the user to convert the measured deltas to atom % off line. The above method has proved quite successful at a number of sites where labelling with $^{15,15}\text{N}_2$ is performed. Obviously these difficult experiments in the general case may render the above approach inappropriate, but the user should be aware of the problems which may result from this NO contamination.

Atom Percent Formulae

We now list, for reference, the atom percent formulae use in the code. Note that these equations assume equilibrium thermodynamics in all cases except for enriched Nitrogen analyses where the 30 AMU intensity is monitored. Even here the Reference gas must be in equilibrium, and this specific case is dealt with above.

Carbon Dioxide

$$\text{APC}(^{13}\text{C}) = \frac{100 \text{ R13}}{1 + \text{R13}}$$

$$\text{R13} = (\delta 1 / 1000 + 1) \text{ R1}$$

$$\text{R18} = (\delta 2 / 1000 + 1) \text{ R3}$$

$$\text{R17} = (0.5 \delta 2 / 1000 + 1) \text{ R2}$$

$$\text{and } \text{APC}(^{18}\text{O}) = \frac{100 \text{ R18}}{1 + \text{R17} + \text{R18}}$$

R1, R2 and R3 are the three reference ratios input into the constants page and refer to 13/12, 17/16 and 18/16 ratios of the international standard.

The same formulae apply to carbon monoxide since we have deconvoluted the δ^{29} and δ^{30} to δ^{13} and δ^{18} .

Nitrogen

The calculation method employed for enriched nitrogen (and samples where the 30AMU signal must be considered) is given above. Here we only consider the case where the 29AMU beam is used.

$$\text{APC}(^{15}\text{N}) = \frac{100 \text{ R}_{29}}{2 + \text{R}_{29}}$$

Thus for hypothetical gas consisting of the international standard:

$$\text{R}_{29\text{calc}}^{\text{ref}} = \frac{2 \text{ APC}^{\text{input}}}{100 - \text{APC}^{\text{input}}}$$

From the observed sample delta (with respect to the international standard used, normally air), a calculated sample ratio $\text{R}_{29\text{calc}}^{\text{sam}}$ is obtained, from which the sample atom percent is calculated.

The APC of the international reference is input into the R1 field in the constants page.

Oxygen

We assume that beams 32,33 and 34AMU are measured and that the data is deconvoluted such that $\delta 1$ refers to delta 17 and $\delta 2$ refers to delta 18. Obviously the deconvolution constants must be calculated to refer to the standard gas being used. The definition of the deconvolution constants used in the program is given above.

$$\begin{aligned} \text{R}_{17\text{sample}} &= (\delta 1 / 1000 + 1) \text{R}_{17\text{ref}} \\ \text{R}_{18\text{sample}} &= (\delta 2 / 1000 + 1) \text{R}_{18\text{ref}} \end{aligned}$$

Therefore:

$$\begin{aligned} \text{APC}(^{17}\text{O}) &= \frac{100 * \text{R}_{17}}{1 + \text{R}_{17} + \text{R}_{18}} \\ \text{APC}(^{18}\text{O}) &= \frac{100 * \text{R}_{18}}{1 + \text{R}_{17} + \text{R}_{18}} \end{aligned}$$

The value of $\text{R}_{17\text{ref}}$ is input into the R1 field and the value of $\text{R}_{18\text{ref}}$ into the R2 field of the constants page.

Sulphur Compounds

Since not all the sulphur peaks (due to S32, S33, S34 and S36) are monitored and there does not appear to be a recommended relationship to correlate the variations of one ratio with another, a general formula for the atom percents cannot be given.

Nitrous Oxide (N₂O)

Here again we assume the observed R45 and R46 ratios have been deconvoluted by the user, calculating the constants for the laboratory standard employed and using the general deconvolution parameters as defined above. We assume further that the data is deconvoluted such that $\delta 1$ refers to $\delta 15$ and $\delta 2$ refers to $\delta 18$.

Then:

$$R15_{\text{sample}} = (\delta 1 / 1000 + 1) * R15_{\text{ref}}$$

Where:

$$R15 = \frac{APC15}{APC15}$$

With the APC15 of the reference gas input into the R1 field of the constants page the value of $R15_{\text{sample}}$ is calculated, and the APC of the sample evaluated using:

$$APC = \frac{100 * R15}{1 + R15}$$

The Oxygen APC is calculated using the same method as with Carbon Dioxide above.

NOTE: The different definitions for nitrogen and oxygen in these fields.

Introduction

The Micromass IsoPrime has been designed as the base component for a modular isotopic analysis system. Its construction is arranged so that all options and accessories can be added to the basic instrument. This provides the important benefit of a simple upgrade path, so that the system can grow to meet the changing requirements of the user. This section describes the core design of the Micromass IsoPrime, including all the components of the basic instrument.

The Micromass IsoPrime is a bench top instrument with a space efficient design. All the major components of the analyser reside within a single cubicle on the bench top. A rotary pump providing roughing vacuum for the IsoPrime is located below the bench.

The result of this arrangement is good ergonomics for a pleasant laboratory environment, with all the main components located for ease of access and maintenance.

The IsoPrime cubicle contains the following components:

- Ion Optics (Mass Spectrometer).
- Inlet isolation valve
- Electronics unit.
- Head amplifier.
- High vacuum pumping system.
- Electrical wiring assembly.

Sample preparation systems are mounted on either side of the IsoPrime cubicle (see the instructions for each interface for specific location requirements).

The Micromass IsoPrime system

Mass Spectrometer

Ion Optics Overview

The ion optics are mounted on top of the IsoPrime case and are contained within a rectangular section vacuum enclosure. The turbomolecular pump extends below the housing within the case. This arrangement provides ready access to the source, collector and isolation valve of the IsoPrime whilst placing the turbomolecular pump within a forced airflow environment. This ensures that the turbomolecular pump is maintained at the correct operating temperature for long and trouble free operation.

The instrument case is formed from folded steel to provide a rigid and stable base for the ion optics.

The ion optics are arranged to have a horizontal geometry. The source is mounted to the right of the instrument (viewed from the front) with the collectors mounted at the left-hand end of the vacuum enclosure.

The design allows easy access to the source and collectors, which may be removed as complete assemblies on their mounting flanges for ease of maintenance.

The turbomolecular pump is mounted directly under the source to give unrestricted high vacuum pumping. This arrangement produces good abundance sensitivity, low backgrounds, and minimum inter-sample memory.

The IsoPrime is supplied with a hood, hinged at the rear of the cubicle that provides protection for the mass spectrometer or may be lifted to allow access to the vacuum enclosure and magnet.

Ion Optics Housing

Ion Source

The ion source uses the tried and trusted ion optics design of the Optima and Prism instruments. It has been redesigned to make it easier to maintain and assemble.

- The part count has been reduced by 20%.
- Filament replacement has been simplified.

IsoPrime-EA User Manual

- The defining slit may now be replaced without disassembly of the source stack.
- Stack ceramics are now shielded from ion burn for increased lifetime.
- Source wraparound and filament shield design simplified.
- Source connections now push-fit.
- Inlet probe now self-locating for better gas tight fit.

Ion source mounted on the source flange

The ion source is a small chamber in which gas molecules are ionised by collisions with electrons. A source using this form of ionisation is referred to as an Electron Impact (EI) ion source.

The electrons are emitted by thermal excitation from an incandescent wire filament, and are accelerated through the source by a small voltage between the filament and source (electron volts) of 50 -100 volts. The electrons are collimated by a narrow electron entrance slit opposite the filament, and follow a helical path through the source under the influence of the magnetic field produced by two small permanent magnets (the source magnets). This raises the ionisation efficiency by increasing the probability of collisions between gas molecules and electrons.

The majority of electrons, which do not cause ionisation, are collected at the Trap (to produce the Trap current). The current through the trap is used in a feedback loop to control the emission from the filament via the filament current. This is known as a trap-regulated system, and provides a constant flow of electrons through the source.

The source block is a machined component that forms the base and two sides of the ion source block. Machined into the side of the source block is the gas inlet aperture, where the ceramic inlet probe admits gas to the source. Adding the wraparound to the source block forms the source 'box'.

The "Wrap-around" is a photo-etched sheet that forms the top, front and bottom surfaces of the ion box. It contains the electron entrance hole (filament side of the source, referred to as top) and exit hole (trap side, referred to as bottom) on opposite faces, and the ion exit slit on its front face.

IsoPrime-EA User Manual

The ion repeller is a flat electrode at the back of the source box, opposite the ion exit slit, which is used to move the region of ionisation with respect to the slit.

The half plates are two electrodes that form an electrostatic lens, which provides a focusing effect on the ions as they emerge from the ion exit slit. The half plates also provide steering of the ion beam in the y-direction.

The defining (source) slit ensures that the ion beam is well defined as it leaves the source and is held at ground potential to collect any scattered ions.

The Z plates are two electrodes that provide beam steering in the z-plane.

The final alpha plate defines the maximum beam width at that point prior to the ion beam entering the flight tube on its way to the collectors.

The source voltages and currents are variable and depend on the gas species to be analysed. These voltages and currents are supplied from the electronics units and controlled via the computer (please see later sections of this manual for details of tuning the source and electronic units).

The connections to the source are made via a number of feedthrough connectors located in the source mounting flange.

Source Feedthrough Connections

Gas Inlet Probe

The gas inlet probe of the IsoPrime is composed of three components and is supported by the inlet probe feedthrough that is welded into the source flange.

The stainless steel inlet tube holder slides within the inlet probe feedthrough and is forced towards the source by a compression spring. The end of the inlet tube holder is tapered internally to accept one end of the inlet tube.

The inlet tube is manufactured from ceramic and is tapered on both ends. One end fits within the tapered end of the inlet tube holder whilst the other end is pressed by the compression spring into the gas entry aperture of the ion box.

IsoPrime-EA User Manual

The tapers on both the ion box and the inlet tube holder are designed so that a line seal is formed between the ceramic inlet tube and the other tapers. This mechanism ensures a self-aligning and gas tight seal for the inlet probe.

Gas Inlet Probe

Analyser magnet

Permanent magnet

The permanent magnet has an 8mm gap and a field of ~5750 gauss. It is suitable for use with a mass range of 20 – 70 daltons. Selection of the mass of interest is by variation of the acceleration voltage. The permanent magnet has been optimised to work best when measuring the species carbon dioxide and nitrogen. As source sensitivity increases with acceleration voltage users will experience a loss in sensitivity as they work with higher mass species.

The IsoPrime permanent magnet

Electromagnet

The electromagnet is designed to operate with a current of 1-5A. The jaws of the electromagnet have been designed to provide full coverage of the ion path when working with widely separated masses, e.g. mass 2 & 3. This also provides a wide focal plane on which may be mounted any required combination of collectors.

The magnet power supply is mounted underneath the electromagnet and is controlled via electronics built into the system controller.

The magnet current is fully adjustable from the computer over the range 0-5A with 16-bit resolution. This provides the IsoPrime with a mass range of 0 - ~100 daltons.

The IsoPrime electromagnet

Both magnets are mounted on the same design carriage. A location plate has three ball bearing castors fitted through it. Mounted on the thread protruding behind the castor is a brass nut that engages in the base of the magnet.

The magnet sits on the three brass nuts and the whole carriage is free to roll about the support plate. The magnet is clamped into position using a bolt from beneath the support plate. The bolt may be engaged in two positions, away from the analyser housing (for magnet removal/replacement) or towards the analyser housing (the operating position). The hole in the forward position is sized to allow the magnet to be moved over the normal adjustment range without removal of the bolt.

When the magnet is in the correct position it may be clamped securely by tightening the bolt. Two adjusting screws provide fine adjustment of the magnet position, one to the left of the magnet and one in front of it. These two screws provide location in the X and Y directions. Rotation of the magnet is constrained by an adjustable bracket on the location plate.

The z-height, pitch, and yaw of the magnet are provided by adjustment of the three brass nuts.

Once the magnet has been positioned correctly and the adjusting screws moved into position, the magnet may be removed from the analyser and returned to the original position with ease.

Magnet carriage

Analyser housing

The analyser housing is manufactured from stainless steel. The grade of steel used ensures low remanent magnetic fields within the analyser.

The housing is rectangular in section with two end flanges sealed with viton seals. The two end flanges carry the source and collectors. The flight tube is integrated into a cut-out in the side of the housing.

The flight tube section is constructed from 1mm thick stainless steel plate to allow the jaws of the magnet to sit around it.

Baffles are fixed within the analyser to restrict unwanted ions from reaching the collectors. The baffles are readily removable for cleaning during normal maintenance.

The arrangement of the integrated flight tube in the housing allows an unobstructed focal plane. This allows a number of masses to be measured simultaneously.

Collectors

The IsoPrime uses the universal collector depicted below for all the gases except for Hydrogen. This provides three individual collectors each with different width resolving slits.

The narrowest accepts the ion beam from the minor 1 isotope and is referred to as the axial collector. The narrow slit gives relatively good resolving power and rejection of stray ions. The slit is wider than the width of the ion beam and therefore the scanned peak shape is 'flat-topped', this reduces errors in the ratio measurements due to small drifts in ion beam position.

Universal collector construction

The larger outer collectors have slits that are approximately three times wider than the axial collector does, they accept the ion beams from the major and minor 2 isotopes. This accommodates the variations in the ion beam separations for the different gases (e.g. CO_2 , N_2), without the need for moveable collector assemblies.

Collector schematic (beam mask)

Electron suppressor plates are fitted to each collector and are maintained at approximately -43V . The suppressor is mounted between the resolving

IsoPrime-EA User Manual

slits and the Faraday buckets in order to minimise ion drift between adjacent collectors and also to reject any secondary electrons generated by ion bombardments.

Each individual collector is mounted on a mounting plate that is in turn fixed to the collector flange. The mounting plate extends along the focal plane of the analyser and allows collectors to be mounted at any point along the plane.

The signal leads from the collectors are double screened to avoid any pickup from unwanted ions and connect to the collector feedthrough inside the collector feedthrough shroud.

Collector housing internal view showing collector wiring

The connections to the collectors and the suppressor supply are made via a single nine pin feedthrough flange. Eight of the pins are available for connection to collectors and the central pin takes the suppressor supply.

Collector feedthrough outside view

Vacuum system

Overview

The pumping system is designed to produce the clean high vacuum required for reliable high precision stable isotope analyses. It also provides the high pumping speeds essential for the high gas flow rates encountered in continuous flow applications.

Analyser pumping system

The analyser pumping system is composed of an Edwards RV3 rotary pump which provides the backing for an Edwards EXT250 turbomolecular pump.

The rotary pump is connected to the IsoPrime by a 2m length of flexible hose. This allows the rotary pump to be positioned at a convenient position behind and below the IsoPrime.

The backing line from the rotary pump is connected to a foreline trap filled with activated alumina. An isolation valve allows the rotary pump to be isolated from the turbomolecular pump, enabling the rotary pump to remain operating whilst the analyser is vented. This ensures that moisture from the air is not adsorbed onto the foreline trap, which will prolong pumpdown times.

The isolation valve and foreline trap is mounted on the rear of the IsoPrime for easy access. For ease of maintenance, the foreline trap is fitted with a vent valve enabling replacement of the packing without venting the analyser.

The rotary pump is fitted with an oil mist filter to prevent unwanted emission of pump oil into the laboratory atmosphere.

An automatic vent valve is fitted to the turbomolecular pump. This ensures that even under conditions of power failure the chances of rotary pump oil entering the analyser are minimised. A filter is fitted to the vent valve to stop unwanted particles entering the vacuum system during the venting process.

The turbomolecular pump is cooled by fans fitted into the case of the instrument. Two fans are mounted on the rear panel of the IsoPrime. One, mounted directly behind the analyser turbo pump and electronics case, draws air into the case and provides cooling for the analyser turbo pump. The other fan, mounted at the other end of the case, extracts air from the case to ensure an airflow from the right of the case to the left.

All the components of the turbomolecular pump are controlled by an EXC100L controller mounted on the left of the IsoPrime.

The source control electronics are disabled until the turbo pump reaches full speed.

Analyser Pump Layout

Caution: Routine maintenance is essential to reliable performance of the IsoPrime. A good, clean vacuum is fundamental for the correct operation of an isotope ratio mass spectrometer. Following the manufacturers recommended service schedule will reap its reward in continued trouble free operation.

Please refer to the maintenance section and the manufacturers manuals for service procedures and intervals for all components of the pumping system.

Pressure Measurement

Penning Gauges

An active inverted magnetron (AIM or Penning) gauge is fitted to the ion optics housing to monitor the pressure of the system. The AIM gauge is mounted on a NW25 elbow beneath the collector end of the housing.

The AIM gauge is controlled and monitored from the electronics unit, which is located at the right of the IsoPrime cubicle. The AIM gauge is enabled as soon as the turbo pump reaches ~95% speed. The software displays the pressure on the computer (see later sections of this manual for details).

Protection against overpressure of the AIM gauge is provided by monitoring the turbo pump speed. Should the speed of the turbo pump drop below 95% the AIM gauge is disabled.

Note: For information on the Penning Gauge control see later sections of this manual for details.

Pirani gauges

An APG S NW16, active Pirani gauge is used to measure the pressure in the analyser pumping backing line. This gauge is located adjacent to the turbo pump roughing port and reads at all times that the electronics unit is powered.

Vacuum protection

The pressure measuring devices, in conjunction with the vacuum control provide vacuum protection for the Penning gauge and ion source.

Any condition that results in overpressure will cause the ion source power supply and Penning gauge to switch off.

Electrical and Electronics

Warning: All electrical and electronic units can cause injury, so care must be taken.

Overview

This section gives a brief description of the functions of each of the IsoPrime's electronic units.

IsoPrime layout (rear view)

The electronic units that may be fitted in the IsoPrime comprise the following:

IsoPrime-EA User Manual

- System Controller
- Turbomolecular pump controller
- Head amplifier
- Magnet Supply
- Bakeout power supply

The minimum configuration for an IsoPrime is the system controller, turbomolecular pump controller and a head amplifier. Other units may be present depending on the configuration of the instrument.

System Controller

The system controller is located inside the cubicle behind the door on the right hand side. This location allows the closest connection of the high voltage supplies to the source; this arrangement imparts the greatest protection to the system against flashover.

The system controller controls all the electronic systems of the instrument. The controller is based around a dedicated Motorola 68000 microprocessor. This provided all the control necessary for the system to operate the instrument.

The data system controls the instrument by communicating with the system controller via an RS232 serial link. There is a constant exchange of instructions and data between these two computer systems.

Incorporated within the system controller are the power supplies and control electronics for the complete instrument. Control functions supported are listed below.

- Active gauge interface for two gauges (pirani and penning).
- Power supplies for instrument cooling.
- Valve control for continuous flow interfaces.
- Electromagnet control.
- Head amplifier power supply.
- Four channels of VFC acquisition for ion beams
- Three additional channel of data acquisition for FID and TCD signals.
- TCD power supply.
- GC and EA start/stop signals.
- Turbomolecular pump controller logic.
- Bakeout control.
- Control of all the source parameters and high voltage supplies

System firmware is written in 'C' and is based upon the well-proven firmware used within the Optima and Isochrom instruments.

IsoPrime-EA User Manual

The systems controller has been designed to be easily removable by the customer and offers the possibility of exchange by the customer on site, thus precluding the expense of an engineer visiting.

Source and High Voltage Supplies

Warning: These units generate the voltages and currents required to drive the gas source. Their function is built into and controlled by the system controller.

High Voltage Supplies

High voltage is produced by three supplies located within the system controller unit. The voltages generated are used to drive the ion source. A total of three supplies are used, one to provide the source HT potential and the other two to provide focus and, by differential offset of the voltage references, half plate steering.

The high voltage supplies are referenced to the ground potential of the instrument.

The system controller board also produces the Z steering voltage.

Source Control Unit

The source control unit is built into the system controller. The source control generates other current and voltage supplies required for the operation of the ion source. The whole of the source control is floated at accelerating potential and superimposes its supplies upon this voltage.

Source voltages and currents generated by the source control unit are:

- Filament current
- Trap current
- Electron volts
- Ion - repeller voltage

Source connections

All the source voltages and currents are attached to the source via cables, which connect into the top of the system controller. The source connections and cable are protected by a cover fitted over the end of the analyser housing.

All source potentials are monitored by the systems controller and may be read back and displayed on the data system.

Head Amplifier

The 4-channel amplifier is housed in a rugged aluminium casting. It is secured to the side of the collector housing by two recessed bolts. Location is aided by two dowel posts on the side of the housing. The connection to the collectors and to the secondary electron suppressor is by a 9 pin gold feedthrough. The connectors in the amplifier are spring-loaded to ensure good contact.

Internally the amplifier is divided into 2 compartments, each housing a printed circuit board. The upper board (the "analogue board") is responsible for amplifying the collector currents by converting them into a

IsoPrime-EA User Manual

voltage (0V to 10V). Prominent on this board are the 4 low temperature coefficient resistors. The resistors used are:

Low Mass 2: 5×10^8 ohms (not used)
Low Mass 1: 5×10^8 ohms
Axial: 5×10^{10} ohms
High Mass: 1×10^{11} ohms

As the maximum output voltage of each amplifier is 10V, the maximum source current can be calculated:

Low Mass 2: 2E-8A (not used)
Low Mass 1: 2E-8A
Axial: 2E-10A
High Mass: 1E-10A

A unique feature of the amplifier is that it digitises the amplified signal prior to transmission. This is performed by voltage to frequency converters on the analogue board. The conversion is scaled such that the full-scale 10V output from the amplifier is represented by a frequency of 1 MHz.

The second printed circuit board is called the 'digital board'. Its function is to turn the digitised signal from the amplifier board into pulses of red light which are then transmitted to the System Controller via optical fibre. The use of a fibre optic link makes the transmission of data immune to external electrical interference.

The system controller is responsible for counting the number of light pulses that arrive at its VFC card in each 100mS integration period. Some simple arithmetic shows that a full-scale signal is equivalent to 100,000 "counts" in each period.

The power supply for the amplifier and the secondary electron suppresser is connected to the digital board via a DIN plug.

Caution: The amplifier contains very static sensitive components. It should be handled carefully. Before removing the amplifier, turn off the source to prevent voltage build-up on the feedthrough pins. Short the nine feedthrough pins to the collector housing (using a screwdriver) before fitting the amplifier back on. Only when the amplifier has been refitted and connected is it safe to switch the source back on.

Caution: Never touch any of the components inside the amplifier, as contamination may produce small tracking currents that could have a serious affect performance. Never attempt to clean the head amplifier components, this will almost certainly result in the same effect..

Electromagnet supply

The electromagnet supply is located directly underneath the electromagnet and is mounted within the electromagnet support. The unit is powered from the electronics mains circuit. It contains a raw DC supply and a programmable DC-DC converter under the control of the system controller.

Turbomolecular Pump Controller

The turbo pump controller (Edwards EXC100L) is situated on the left of the instrument. It is connected to the system controller for speed readout and on/ off control. For more information about the controller refer to the manufacturer's instructions.

Mains distribution

The power supply for the IsoPrime is provided by a single IEC connector located on the rear left of the instrument. This power input is connected to an IEC distribution block mounted on the rear panel of the IsoPrime. Connection leads from this block provide power to the various electronic units fitted to the instrument.

The mains circuit is protected by a double fused IEC inlet connector. Fuse ratings and type are clearly indicated on the rating plate of the instrument.

Caution: Under no circumstances should electronic units other than those fitted within the IsoPrime cubicle be connected to the distribution block. Failure to observe this precaution may result in overloading of the mains supply system.

See the fault-finding section for details of all fuses in the system.

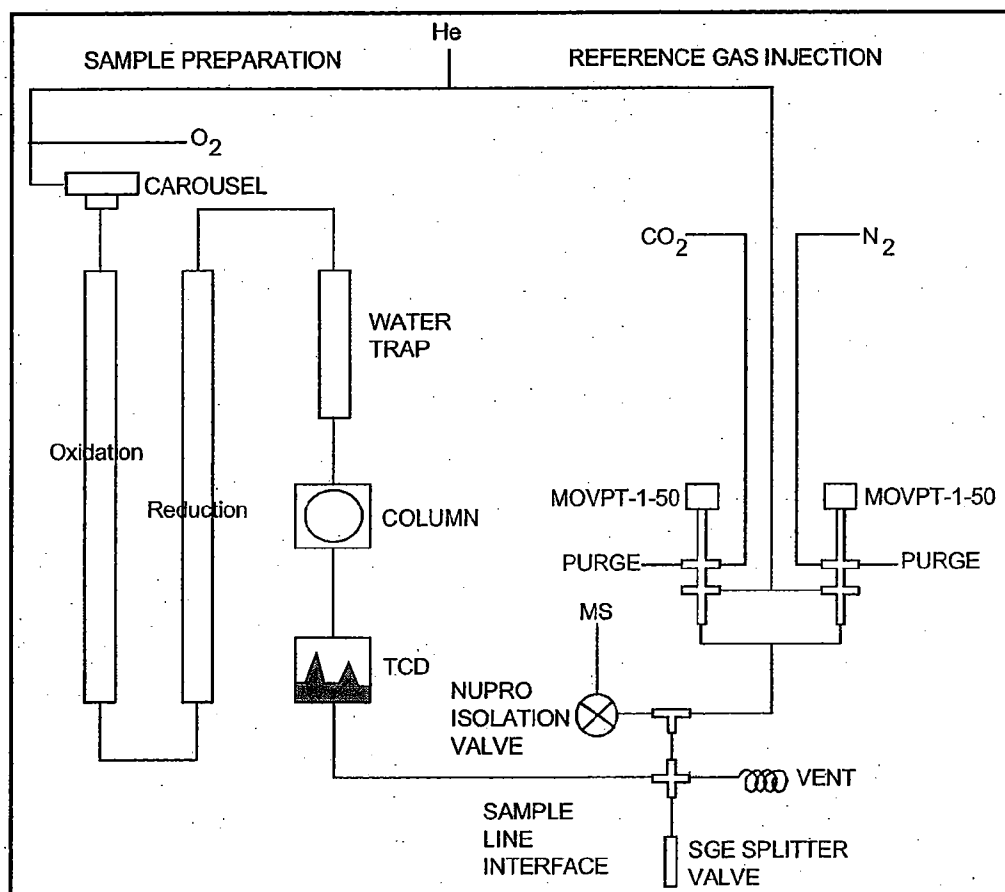

The EA interface

Overview

The EA interface system comprises a number of different units, each designed to perform a specific function within the sample preparation-analysis cycle. A figure of the system is shown below.

The units are:

- The elemental analyser for the combustion of samples and the separation of resulting gas species N_2 , CO_2 , SO_2 .
- The IsoPrime interface for establishing the conditions under which sample and reference gases are presented to the mass spectrometer.
- The IsoPrime mass spectrometer previously described.

The Elemental Analyser

The most common type of elemental analyser fitted to the system is the CE Instruments NA2500. Most options associated with this analyser can be implemented. A full description of the NA2500 along with a list of available options are contained within the manufacturer's product manual supplied with the instrument.

Reference Gas Injector

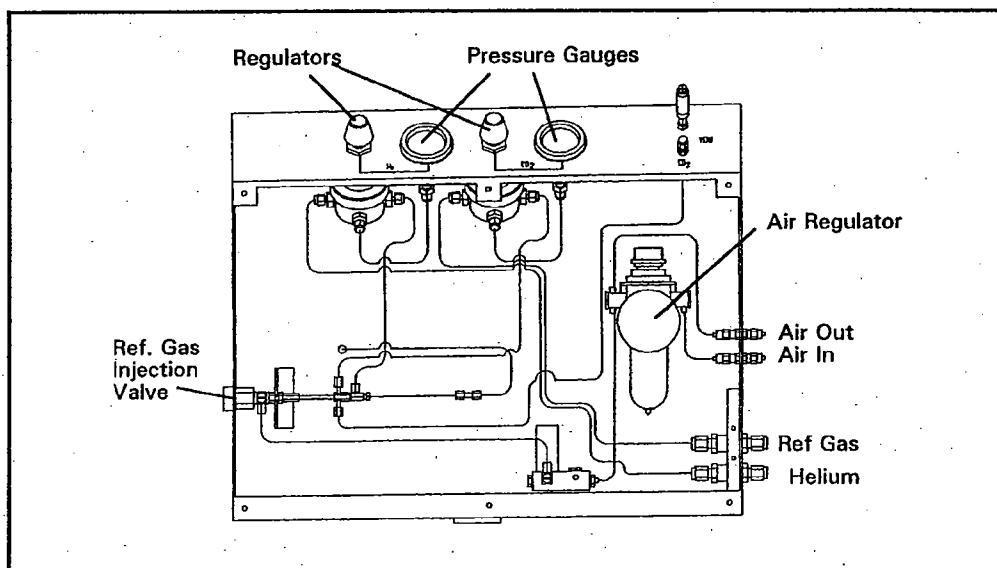

The reference gas injector is designed to introduce stable pulses of pure gas of known isotopic composition into the analyser at constant intensity, for the purposes of system calibration. There are two forms of reference gas injector:

- Single gas injector capable of delivering pulses of one species of reference gas
- Dual gas injector capable of delivering pulses of two species of reference gas

Both types of injector require supplies of each species of reference gas and of Helium carrier gas. Details of the quality of gases required are given in the site planning guide found in the Appendices section of this manual.

Single gas injector unit

The schematic for the single reference gas injector is shown in the figure below.

Single Reference Gas Injector

The system comprises an outer single reference gas box assembly in which are enclosed:

Reference Gas Injection Valve

The reference gas injection valve releases (mnemonic is RG) reference gas into a continuous stream of Helium. The gas flow from the reference gas injector is sampled by the mass spectrometer. A schematic of the reference gas injection valve is shown in the figure below.

Reference Gas Injection Valve

The valve body is an SGE MOVPT 1/50 normally closed needle valve actuated by compressed air (see manufacturer's product information). At the base of the valve sits a back-drilled, SGE VG-GVF 003 ferrule, into which is fitted a 70mm length of 25 μ m ID fused silica capillary. The end of the piston plunger shaft acts on the top face of the back-drilled ferrule. When the compressed air is on, the end of the shaft is lifted off the back-drilled ferrule, allowing reference gas to flow down the 25 μ m capillary to mix with the continuous stream of reference Helium introduced through the SGE VG-MFT 16 tee piece attached to the end of the MOVPT valve. The gas mixture passes through an 8cm length of stainless steel 1/16x0.006" capillary, and flows into a length of stainless steel 1/16x0.030" capillary into which are inserted the reference gas and standby fused silica capillaries. Instructions on the fitting of these fused silica capillaries are given in the Maintenance section of this manual.

The Gas Network

The reference gas and reference Helium pressures are controlled by regulators mounted on the top of the reference gas injection box. The Helium and reference gas sources are connected to the rear of the reference gas injection box via an in-line filter. The gases flow directly to manual pressure regulators, 0 - 10psi for the reference Helium and 0 - 30psi for the reference gas. The gas pressures are read from pressure gauges mounted in the top of the reference gas injector box. The reference Helium flows to the exit capillary via the reference gas injection valves. The reference gas flows to the tee assembly at the end of the SGE MOVPT 1/50 valve and hence to an exit vent situated at the top right of the reference gas injection box. The rate of flow from the reference gas vent is controlled by an adjacent SGE BMCV-1 needle valve.

The Compressed Air System

The reference gas valve (mnemonics are RN for N₂ and RG for CO₂) is actuated by compressed air delivered from a suitable supply through a bulkhead fitting situated on the rear of the reference gas box. The compressed air is unregulated and must be supplied suitable regulated and filtered according to the details laid down in the site requirements guide. The compressed air supply passes to the reference gas valve via a normally closed Predyne valve. The firmware address and mnemonic for this valve varies depending on whether the reference gas injector is designed for Nitrogen or Carbon Dioxide. A 25-way D-type plug allows the reference gas box to be connected to the system controller for operation of the valves. Activation of the Predyne valve sends compressed air, at 55 psi, to the reference gas valve. This lifts the piston plunger in the reference gas valve and allows reference gas to be introduced to the Helium stream, and hence to the mass spectrometer.

Dual gas injector unit

The dual reference gas injector unit is similar in design to the single type. However, it is capable of dispensing two gas species, usually N_2 and CO_2 . The schematic for the dual reference gas injector is shown in the figure below.

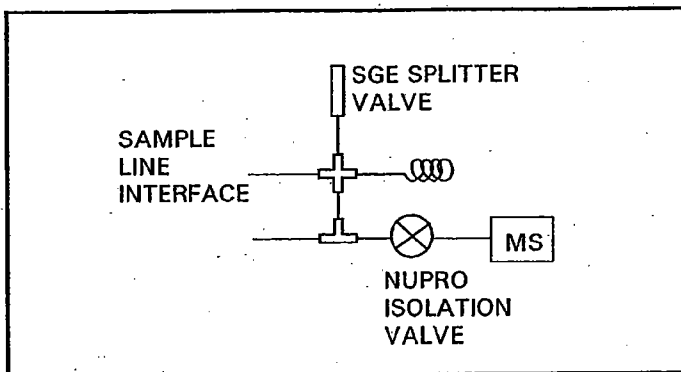

Dual Reference Gas Injector

Sample/ reference line interface

The sample/ reference line interface for the EA comprises the following components:

- EA outlet connection fitting.
- Sample splitter valve assembly.
- Sample and reference fused silica capillaries.

The sample flow from the elemental analyser is passed to the splitter assembly via the outlet connection fitting. The SGE splitter valve allows a small but variable amount of the sample flow (normally approximately 0.3ml) to pass to the mass spectrometer. The reference gas flow is introduced via a tee on the base of the splitter valve assembly. A fused silica restriction capillary (2m of 75 μ m ID) is used to restrict the amount of gas entering from the reference flow to account for approximately 1/10 of the total flow into the mass spectrometer. Both the sample and reference gas flows then pass through the Nupro isolation valve into the mass spectrometer ion source.

The Gas Distribution

The following gases are required for the operation of the EA interface. Details of the necessary quality for these gases are given in the site planning guide in the Appendices at the end of this manual. The gases required are:

Elemental Analyser

- Helium Carrier gas for the EA.
- Oxygen Required for the sample flash combustion process.
- Air (compressed) For operating the sample carousel.

Reference gas injection

- Helium Carries reference gas to the mass spectrometer
- CO₂ Isotopic reference gas.
- N₂ Isotopic reference gas.
- Air (compressed) For operating the valves.

Note

The gas cylinders should be located as close to the instrument as possible and connected using 1/8" stainless steel tube.

Utility gas requirements.

Note: Gas pressure in units of bar.

| | Helium | Oxygen | Air | CO ₂ | N ₂ |
|-------------|--------|--------|-----|-----------------|----------------|
| NA 2500 | 4 | 4 | 3 | n/a | n/a |
| Ref gas box | 4 | n/a | 3 | 4 | 4 |
| Purity /% | 99.999 | 99.999 | DRY | 99.999 | 99.999 |

Operational Overview

The EA interface is based around the principle of interfacing the effluent flow from a standard elemental analyser directly into the ion source of a mass spectrometer in order to provide isotopic information in addition to the quantitative information already available from the elemental analyser.

CE Instruments NA2500 Elemental Analyser

Mode of operation exactly the same as described in system operating instructions. The EA functions as an on-line prep system for the production of N₂, CO₂, SO₂, H₂O from solid or liquid samples.

Samples are loaded on to the carousel and sequentially dropped into the combustion furnace. A pulse of oxygen promotes a flash combustion of the sample at 1800°C. The resulting gases are swept through a reduction furnace, converting oxides of nitrogen to nitrogen. Water of combustion is removed by a chemical water trap. Nitrogen, Carbon Dioxide and Sulphur are then separated spatially in time by a packed GC column. The amount of each species is measured by a thermal conductivity detector connected to some type of integrator. The time taken for any analysis is dependent on - the length of the GC column, its temperature and the flow rate of the helium carrier gas.

Interface

Designed to sample the effluent helium stream from the NA2500, introduce a portion of the stream in a safe manner to the mass spectrometer ion source and enable the introduction of a reference gas pulse for isotopic comparison.

The sample line flow of about 100ml per min coming from the elemental analyser is connected to an SGE splitter valve. The function of this valve is to control the amount of sample line helium actually flowing into the mass spectrometer source. In normal operating mode, this would be about 0.3ml per min giving an analyser pressure of 3E-6 mbar. Altering the flow rate into the source allows more or less sample into the source. Once the interface split has been set the SGE valve should, if at all possible, not be altered due to the length of time required for it to settle to a steady split. The flow from the SGE valve is connected to a tee into which is brought, the reference gas capillary from the reference gas box. The capillary is pushed 6cm past the tee toward the mass spec prior to tightening the ferrule.

The reference capillary consists of 2M of 75um ID fused silica quartz capillary, one end of which is pushed 30cm up the inside of the 1/16" by 0.030" s/s capillary coming from the reference gas box. This capillary samples the reference gas stream in an open split configuration and on its own would produce a pressure in the analyser of about 5E-7mbar. The amount of reference helium or reference gas sampled depends on the length and ID of the capillary and the relevant gas pressures as set in the reference gas box.

Reference gas injection

The function of this component is to provide reference gas pulses for introduction to the mass spectrometer.

The Autosampler Carousel

Minimum capacity of 50 samples. Can increase capacity to 196 samples by the addition of 3 more sample drums.

TCD Operation.

The EA interface has the ability to measure elemental composition using the TCD of the elemental analyser or the mass spec detector.

Data System

Because of the rapidly changing nature of the PC market it is not possible to give a specification of the data system used here as it would rapidly be obsolete.

In general terms the data system will have sufficient power to run the OS/2 operating systems required for the software and have at least one serial port for communications to the mass spectrometer.

A dot matrix printer will also normally form part of the data system.

The data system is connected, by a serial cable to the rear of the mass spectrometer.

Please refer to the manuals supplied by the manufacturer for more details about the data system.

IsoPrime - EA User Manual

Overview

The 'user interface' is the way the user interacts with the mass spectrometer from the computer system. This section of the manual will therefore detail the essential aspects that are needed to accomplish this, however it will be necessary to read the OS/2 manuals supplied with the instrument to complement this section.

Its purpose is therefore to guide the user through the features necessary in running the IsoPrime - EA software, and in conjunction with the context sensitive HELP facility, enable the user to learn the basics of the software that will lead to instrument operation in the next section of this manual. The screen displays are used to familiarise the user with the appearance of the user interface.

OS/2 Environment

This section of the manual cannot serve as a full guide to all the powerful features provided with the OS/2 operating system, but is intended to give the user the basic features required to start running the IsoPrime - EA software package.

Note: PLEASE READ THE OS/2 MANUALS SUPPLIED WITH THE SYSTEM.

The IsoPrime - EA is controlled largely through the use of a 'mouse', pull down menus, and graphical representations of the system called 'icons'. There is no need to learn complicated keyboard sequences, and the system is easy to operate. Some people may prefer to use the Keyboard: there are simple 2 key alternatives to virtually all "mouse" operations. "Hot Keys" give simple access to frequently required options. The Keyboard is of course used in any case to enter data, such as sample names, reference gas compositions, to set integration times etc.

Computer Start Up

OS/2 preserves the layout of the Desktop even when switched off. This means the user no longer have to move icons to the top of a list to get them to start automatically - anything open at shutdown will be opened again next reboot. As well as leaving applications open at shutdown the user can place applications in the start-up folder, these will then be started each time at reboot.

Automatic Start-up

To start an application automatically simply drag the application icon (e.g. EA) into the Start-up Folder (in the OS/2 System Folder on the Desktop). For example to start-up the system clock automatically: - Open the OS/2 system folder. Open the System Setup and the StartUp folders. Now pick the Clock icon from System Setup and Copy it into the StartUp folder. This application will now be run each time the system reboots.

StartUp Problems

As OS/2 will always start applications that were running when it was Shutdown, it is possible to get problems. However, it is possible to disable the automatic program startup. To do this reboot the machine and when the white screen first appears press and hold the left Ctrl, left Shift, and F1 keys. Hold them down until the icons appear on the desktop.

Computer Shut Down

Why?

To speed up access to commonly used files and applications OS/2 now uses a Caching system. A Cache is an area of memory set aside for the storage of data. This means that some files are accessed and left open, stored in the Cache. Any reference to these files accesses the copy in memory (in the Cache), thus saving the time to search and load from disk. When the computer is switched off, or re-booted, the contents of this memory disappears, possibly losing data or corrupting files. Wherever possible before turning the machine off or rebooting the user should perform the Shutdown operation. This will clear the Cache saving any changes and closing files.

In addition to clearing the Cache shutdown will close down all the applications and folders which are open. OS/2 keeps track of the layout of the Desktop, where the folders are and what applications are running. Next time the user boots into OS/2 these will be opened automatically and the Desktop will look exactly as it was at Shutdown. This means ALL folders/programs open at Shutdown will be opened again. The more applications open the slower the system runs so any folders that are not wanted to be opened next time should be closed BEFORE performing the Shutdown (see Window List section).

Note: Some applications will ask for confirmation to close down - this ensures that data is not lost in applications mistakenly left open.

How?

On the desktop, move to an area away from any icons. Bring up the Desktop menu (single click Right mouse button), and select shutdown. Wait for the message Shutdown Completed. The user can now reboot or switch off the computer.

OS/2 Desk Top

On starting the computer the first screen to be seen is the OS/2 Desk Top, an example of which can be seen below. From this, access to any of the applications can be achieved by using the mouse to click on the various icons displayed.

Desk Top Environment

Each application started runs in its own window and a number of application windows can be open on the desk top at any one time. The screen can therefore be used by a number of Windows, which each display information related to a specific area of the software.

One helpful way of thinking about this is to regard the windows as sheets of paper on a "DESKTOP" represented by the whole screen display. Just like paper on a desktop, the windows can be picked up and moved around, put on top of each other etc. Unlike sheets of paper, some of the windows can be shrunk or expanded, either to fill the entire screen, or to occupy a minimum amount of screen space.

The entire IsoPrime - EA program is itself a Window. If the user wishes to run another program, such as a spreadsheet, as well as the mass spectrometer, the IsoPrime - EA window can be sized to suit the display needs. It can even be shrunk to an Icon, and run in the background while the whole screen is available for other applications.

Using the mouse

The mouse is a device incorporating a tracker ball, which moves a pointer around the screen. The mouse pointer is the 'hand' that picks things up and moves them around on the desktop. The mouse also has two buttons at the top that can be depressed (clicked). The left mouse button is the most used button. It is used for selecting, resizing, dragging, copying objects and starting applications etc., within the IsoPrime - EA software. The right button is used for moving objects and setting their attributes.

Clicking

When the pointer is over the menu item or icon that you wish to select, a press or "click" on the left mouse button will highlight that item.

In the case of the main menu bar, clicking on one of the menu options will 'pull down' a further menu. Use the mouse to highlight the option wanted. A further click will then action that option. It is possible to do this more quickly by doing two button presses in quick succession. This is called 'double clicking'.

More detail of Clicking is given below:

- **Single Clicking (with the left mouse button)**
Single clicking on an object (icon, window, or menu) will select it, highlight it. This means that the object now has input focus (i.e. it will respond to anything typed at the keyboard and the other objects won't) or is just selected (depending on what type of object it is).
- **Double Clicking (with the left mouse button)**
Double clicking on a program icon will start that program, (double clicking on a valve icon will open that valve or close it).
Also it is worth noting that double clicking on the small icon in the top left corner of a running application will generally close the application (this is the same as single clicking here and selecting close).
- **Single clicking (with the right mouse button)**
When the user single clicks on a menu name this will bring up a menu list (can also use the left mouse button). The other place this is used is when closing down the system.

- **Double Clicking (with the right mouse button)**
This has no effect.
- **Pressing both buttons together**
This only has effect if the mouse pointer is currently pointing at the desktop, it will bring up a list of all of the programs currently running on the system (see Window List).

Note: Use right mouse button to move icons, etc. and the left button to drag windows.

Dragging

To drag an object (essentially move it), position the mouse pointer over the object and press and hold down the right mouse button, now when the mouse is moved the object will move with the mouse pointer. Care must be taken however when dropping the object.

The most important uses of dragging are:

- **Window Positioning:** any window with a Title Bar can be repositioned by dragging on the title bar.
- **Window Sizing:** a window can be expanded or contracted by dragging on its borders. Dragging on the corners will size in two dimensions simultaneously.

Note: The mouse pointer changes to a double-headed arrow to show that it is possible to resize.

- **Using Slider Bars.** Slider bars are used to scan through long amounts of text in text windows (e.g. Help Index), and in two important parts of the IsoPrime - EA software: Message list and source tuning.

Note: It is also possible to move an object to another location by selecting the move option from the System Menu.

Windows

All Windows have the same features and can therefore be discussed generally, however the IsoPrime - EA software is being used in this example. Windows can have other windows running in them, with the highest level known as the 'Application Window' and the inner windows known as 'Child Windows'.

The entire IsoPrime - EA software runs as an 'Application Window'.

At the top is the 'Title Bar'. At the left end of this is the 'System Menu'. At the right end are the 'Minimise' and 'Maximise' boxes. The System Menu has the following features, which appear as a menu list by clicking once in the System Menu (please beware that a double click will close the IsoPrime - EA software down, double clicking in most System Menus will close that particular application down):

| | |
|-----------------|----------|
| Move | Alt+F7 |
| Size | Alt+F8 |
| Minimize | Alt+F9 |
| Maximize | Alt+F10 |
| Hide | Alt+F11 |
| Close | Alt+F4 |
| Window List | Ctrl+Esc |
| Arrange Windows | |

- Restore**
 If an application has been resized then the clicking in restore will restore the window to its default / original size.
- Move**
 This enables the window to be moved around the screen, the window follows the mouse until the left or right mouse button is clicked (see also dragging a window).
- Size**
 This is used to change the size of a window, by selecting size and moving the mouse pointer to one of the window borders that border will be picked up and move with the mouse until the left mouse button is clicked (see also sizing a window).
- The next three commands can either be found in the menu or in the top right hand corner of a window as icons for maximising, minimising and restoring.

- **Minimise**

This is used to minimise a window to an icon. When a window is minimised the particular 'Minimise' icon for that window is placed in the 'Minimise Icon Viewer' folder.

- **Maximise**

This is used to maximise a window to its largest possible size.

- **Restore**

The restore icon can be used to 'restore' the window to its original size, for example, if the user were to maximise, or indeed re-size the IsoPrime - EA window and then wished to return to the original window size then this can be achieved with the 'Restore' icon.

- **Hide**

This is not used by the IsoPrime - EA software and hence is 'Greyed Out' (see section on Greyed Out).

- **Close**

This is used to close the application window down, ending any programs running from that window.

- **Windows List**

This opens the 'Window List' dialogue box which lists the active programs (also possible using <CTRL. .ESC>).

- **Arrange Windows**

This is used to arrange the windows 'Child Windows' in the 'Application Window', hence tidying the screen layout.

Moving Between Windows

It is often needed to move between windows to view or change information.

To move between windows when the window wanted is visible:

- Click anywhere in the window that is required.

The software activates the window and brings it to the front if there are other windows covering it. The active window has a coloured border and title bar, inactive windows are monochrome. This window now has 'input focus'.

Dragging A Window

Windows can be moved to any location on the screen by dragging them to a different location. This is achieved by:

1. Move the mouse pointer to the title bar of the window to be moved.
2. Press and hold down the left or right mouse button.
3. Drag the window in the direction for it to be moved.
4. When the window is in the new location, release the mouse button.

Sizing A Window

The windows can be made smaller or larger, by moving the borders of the window in or out.

1. Move the mouse pointer to the border of the window (the pointer changes shape to a double arrow when it is in position).
2. Press and hold down the left or right mouse button.
3. Drag the border in the direction desired.
4. When satisfied with the new size, release the mouse button.

Note: Going to the corner of a window enables the window to be re-sized in two directions at once.

Icons

Icons are small picture symbols used to represent either graphical objects (valves, etc.), or windows. An icon which represents a window or application has the name of the application beneath it. When a window is minimised it is represented by its Icon. Within some windows, notably the 'EA Child Window', icons are used to represent real objects, such as valves, etc. (clicking on these icons can produce an action or open a dialogue box).

Iconising A Window

When any of the child windows are minimised, they will appear in the ICON AREA at the bottom of the main IsoPrime - EA window. Windows that can be iconised are the Message Window, the Scan Window, the Data Acquisition Window and the EA-IRMS Window.

Restoring an Iconised Window

A double click on the icon and the window will be restored to its previous size. If the iconised window had a System Menu, a single click on the icon with the right mouse button will access a menu with options to restore, reposition or maximise the window.

Using The Keyboard

Selecting Menus

Each of the Main Menus has an underlined letter. Keying this letter whilst holding down the ALT key will select that menu. Items within the menus can also be selected by using the underscored key.

Note: The System Menu is selected by ALT SPACE.

Moving the menu selection bar

The selection bar can be moved with the cursor keys. When the desired option is highlighted (shown in black), it can be actioned by pressing the return key.

Dialogue Boxes

Movement between entry fields in Dialogue boxes is achieved by using the TAB key and cursor keys. The buttons in dialogue boxes such as Yes, No, Help, etc., are controlled via pressing ALT and the underlined letter or using the cursor keys to give focus to the key needed to select and then pressing the return key.

Special Keys

Certain keys have special applications, or have been allocated as "Hot Keys" which speed up software operation without needing to use the mouse. These are listed and explained below.

- **F1**
The F1 key will open the Help Window. If detailed Help is available for the part of the software that is being used, the appropriate Help Text will be displayed.
- **Esc (Escape)**
This will remove the Help Window and most dialogue boxes without causing any action.
- **Enter (or carriage return)**
Usually this will action the OK or Run Button in a dialogue box.
- **Tab**
This key is used to move between different fields in Dialogue Boxes.
- **Cursor Keys**
These are used to move within dialogue box fields, and between Menus and Commands.
The arrow keys give a fine adjustment, the Page Up and Page Down Keys a coarse step.
- **Alt**
Holding the Alt key down while keying the Underlined letter in a Menu or Command will select that option.
- **Control**
The control Key is used in the same way as the ALT key to access certain commands quickly:
 - Ctrl + C - performs a Peak Centre
 - Ctrl + I - opens the Identify peak dialogue box
 - Ctrl + J - starts a peak jump
 - Ctrl + Q - performs the peak quality routine
 - Ctrl + R - Runs an analysis
 - Ctrl + S - Stops a scan and closes the Scan Window
 - Ctrl + X - Opens the Scan Parameters library

Menus

Menus are a list of functions that can be accessed by selecting the menu item from the list. After selecting (clicking on the menu item or using one of the special keys) some action will take place or the software will require some further information from the user or further menus will be revealed.

Note: If a menu or button has a '...' it means that there is a dialogue box activated by this menu or button, rather than starting a task.

The menu lists will be discussed in further detail in later sections of this manual, however there are some features of menus that need to be discussed at this stage.

Menu Tick (On/Off)

When a tick appears at the left-hand side of a menu item then that function is selected, when the menu item is again selected the tick will disappear hence de-selecting the menu item function. This therefore indicates the application of a toggle type function on the menu item. An example this can be found on the 'Zoom In' menu item in 'Scan Display Window' (see later for details of Scan Display Window).

Sub Menu Arrow

If an arrow appears on the right hand side of a menu item then that item will have a sub menu. Therefore another menu will be below the original menu. An example of this can be seen in IsoPrime - EA software 'Help' menu option 'Language'.

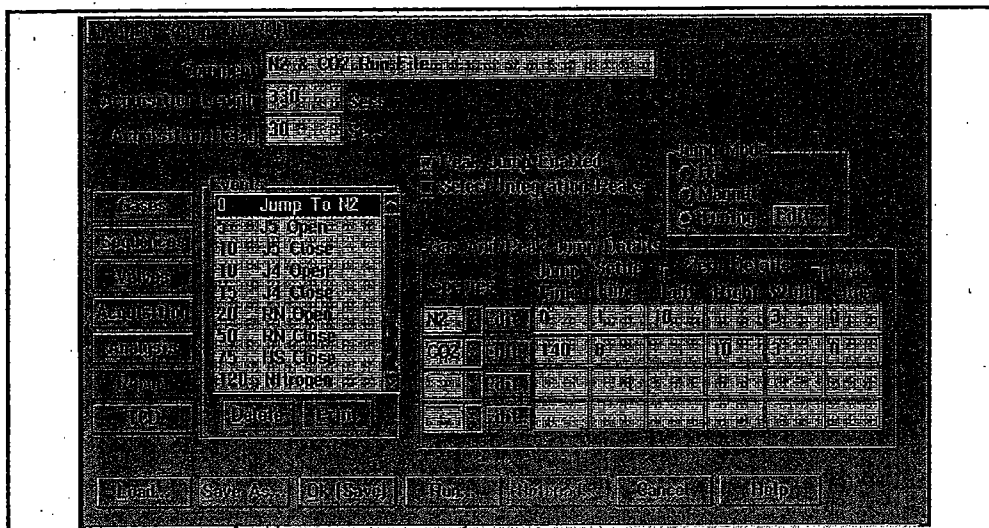

Grey Menu Items

If a menu item appears grey instead of black, then that menu item cannot be accessed at that time. An example of this can be seen in the System Menu when the window is at full screen the 'maximise' option is greyed out, as this has no function when the window is already maximised.

The User Interface

This section of the manual describes the input controls available in OS/2, however the examples will be taken from the IsoPrime - EA software. The main example will be the Method Set-up Dialogue Box as this shows most of the required controls.

Dialogue Box

Dialogue boxes are windows through which the user can answer requests for data or provide information. They may contain any of the controls to be discussed later in this section, for example: entry fields for text or numerical input, push buttons for Help, To OK or Cancel an action, and 'Check Boxes' or 'Radio Buttons' to select or de-select options.

Dialogue boxes generally do not have System Menu and can therefore not be minimised, etc. This generally means they take precedent over any other function and must be answered or cancelled prior to other user operations.

The operational sequence facility available in the software enables the user to create dialogue box questions for instrument control.

Radio Button

These have an on / off function if they are on their own, however the more usual example is as part of a list within a box, where if one function from the list is chosen, the other functions are de-selected (there can be various boxes each containing a different set of radio buttons). In the example, in the "Fit Type" compartment, if 'Polynomial' is chosen then 'Spline' is turned off, and visa versa. A radio button is selected by clicking on the circle next to the item description, on is indicated by a solid black dot in the centre of the circle.

Check box

These have a toggle function where the option is selected or not. Selection is shown with a tick or a cross in the box and is achieved by clicking on the box next to the item description. An example of this appears in the "Method Set up" window shown previously. A tick appears on the left-hand side of "Bknd Subtraction", indicating that background subtraction will be performed when this method is used.

Push Button

These perform a command when selected, for example saving data, calling the help file, opening another dialogue box, etc. The default Push Button is emphasised by a heavy border and is selected by simply pressing the keyboard Return key.

List Box

This gives the user a list of options to be chosen from. These appear in alphabetical order and can be selected with a double click or by a single click followed by a command (Push Button). If the list is longer than the box the list can be scrolled up and down using the scroll bar at the side of the list. The items are selected with a single click and activated with a double click.

Entry Field

This is an area set aside to accept user-inputted data into the dialogue box, for example file names, data, etc.

Combo Box

This is a combination of an entry field and a list box. When the arrow at the side of the box is clicked on a list box appears from which the various options can be selected as with a list box. Alternatively if the user knows the option name then this can be typed directly into the entry field of the combo box.

Scroll Bar

This is sometimes known as a slider bar and can be horizontal or vertical. The purpose of the Scroll Bar is to move a list. An example of a scroll bar appears in the "Method Setup" window. The complete list of "Events" can be examined by moving the Scroll Bar up and down.

Clicking on the arrows will move the slider a small amount, clicking to the side of the slider moves the slider a medium amount and if large moves are required then drag the slider by clicking and holding down the mouse button and moving in the direction required.

Tab

It is possible to move between entry fields in Dialogue boxes by using the TAB key and cursor keys.

Greyed Functions

If a function is in grey text rather than black text, then that function is not available at this moment. For example if the datalogger is disabled then the datalogger options are not required and are therefore greyed out.

Printing

When a job is sent to the printer then a print job object will be created within the printer folder. This print job object represents your print job in the queue. It is possible to view any queued jobs by double clicking on the icon.

Note: If the spooler is disabled then jobs are sent directly to the printer and they will NOT appear in the printer folder.

There are a number of ways that a job can be printed:

1. The application that is running generates a print job.
2. Use the Print facilities available in the software.
3. Use the 'Print' command from the DOS or OS/2 command line.
4. Drag an object and drop it onto a printer object.
5. Position the pointer over the dialogue box or window that is to be printed and press the "Print Screen" key to dump the dialogue box or window to the printer.

Multitasking

The multitasking capabilities extend the power of the software enormously.

These are of two levels of multitasking.

First, each program that runs under OS/2, such as the IsoPrime - EA software, may be "multithreading" i.e. many processes can be active simultaneously. For example the user can be performing an automatic analysis whilst preparing samples on another part of the system, carry out data acquisition simultaneously with any other activity, tune the ion source whilst scanning etc.

Secondly, the system has true "multitasking" i.e. more than one program or "application" can be running at any given time. For example the user can be running the instrument at the same time as analysing data with a spreadsheet and whilst writing a report with a word processor.

IsoPrime - EA Operating Environment

This section of the manual will specifically describe the IsoPrime - EA Operating Environment. Some of this section will however have been described as examples in the previous section on the OS/2 Environment.

Screen Layout

The entire IsoPrime - EA software runs as an 'Application Window' with various 'Child Windows' running inside it. The application window and/or the child windows can be resized to fill the entire screen area, or they can be resized/repositioned to occupy any amount of the screen area. For example, the screen area used by the IsoPrime - EA can be reduced if you are using a spreadsheet application. The window can be minimised and run as an icon if desired.

The Application Window and its child windows form three main areas.

Below the Menu Bar is the Monitor Window, which contains numerical and graphical readouts of the ion beams and vacuum gauges. This cannot be moved, resized, or iconised.

Below the Monitor Window is the main work area of the IsoPrime - EA software. The Message Window appears in this area. Additional windows, and dialogue boxes, etc. will appear here as the software is used.

At the bottom of the screen are windows that contain representations the appropriate preparation system valves, etc. fitted to the machine (EA, etc.). These are user definable and will depend on which inlet and/or preparation systems are fitted. They can be minimised to icons if required.

Main Menu Bar

The diagram below shows the Main Menu Bar from which gives the operator gains access to the rest of the pull down menus available in the IsoPrime-EA. The Main Menu Bar is therefore the primary menu.

Choosing Commands Using The Mouse

For example, to choose the Mass Spec, Tune Source command:

Click the Mass Spec menu option in the Menu Bar.

The Mass Spec menu appears with a list of commands.

1. Click the desired command, in this case, Tune Source
2. After the command has been clicked, the menu disappears. The command will either perform an action or display a dialogue box to get more information from the user.
3. Click the cancel button to cancel a dialogue box.

Choosing Commands Using The Keyboard

Using the same example as above to choose the Mass Spec, Tune Source command with the Keyboard:

Notice that there is an underlined letter in each of the menu names. For the Mass Spec menu, the underlined letter is an M.

1. Press ALT and hold down and type the letter M.

The Mass Spec menu appears.

Some of the commands in the menu have an underlined letter. For the Tune Source command, the letter T is underlined

1. Type the letter T to choose the Tune Source command.
2. Press ESCAPE to cancel a dialogue box.

The Monitor Window

The monitor window is situated just below the Main Menu Bar at the top of the screen. Unlike the other windows, it cannot be resized or iconised. It is used to display important information about the mass spectrometer. The right hand half shows the vacuum gauge status (Numeric and Graphical Displays), and the left hand half shows the Ion Currents and TCD signal size (Numeric and Graphical Displays), as well as the information on the Current Mass (mass in the axial collector) and the date and time.

Vacuum Gauges

The right hand half in our example shows the readings from one Pirani gauge and from a Penning gauge.

Note: This area can display up to 5 gauges that are user definable.

The pressure in millibars is shown next to a horizontal bar that gives a graphical readout of the pressure. The bars are colour coded: green indicates pressure in the normal safe range, yellow a warning of high pressure, and red indicates an unsafe high pressure.

Ion Beams

The signal from 3 Faraday Detectors is shown as Amps to the left of a horizontal bar that gives a visual impression of the beam intensity. The bars are on a logarithmic scale.

The Message Window

The message window appears in the left hand half of the central screen area. It can be resized or iconised if required, but has no System Menu and therefore cannot be closed down. This window is used to display text messages from the software. It is possible to send messages to the text window from other programs.

The message consists of a time for the message followed by the text. After the display portion of the window is full, it is possible to step backwards and forwards through the messages via the scroll bar at the right hand side of the window. This window forms a commentary on the operations performed which provides a record of all events since the program was first booted up.

The Mimic Diagram Window

The Mimic Diagram window normally appears at the bottom of the screen area. It can be resized or iconised if required, but as with the message window it has no System Menu and therefore cannot be closed down.

This window is used to display the graphical representation, made up of icons, of the sample preparation system. The preparation system can be extended or modified by the user to allow for expansion of the system.

Some of the icons are interactive, allowing operation of them by pointing the mouse at them (the mouse pointer will change shape when correctly positioned over the icon) and clicking once with the left mouse button. This will bring up the dialogue box for the icon allowing for example valve operation.

Valves

Use the mouse to point to the desired valve in its mimic diagram window.

Note: the pointer will change size when in range.

Click on the valve icon and the 'Valve Control' dialogue box for that valve will appear, the radio buttons close or open will be selected in the opposite state to the valve.

To toggle the valve either (i) click on the 'OK' push button or (ii) press the return key on the keyboard.

Note: The radio buttons 'Close' and 'Open' can be disregarded as the valves toggle i.e. if the valve is open the next valve dialogue box 'OK' will close the valve and vice versa.

The 'OK' push button appears at the current pointer position, so in practice, a double click toggles the valve.

The Valve control dialogue box also has the following push buttons:

- 'Cancel' will exit the dialogue box without taking any action.
- 'Help' gives information on the operation.

IsoPrime - EA Menus

Across the top of the Main Window is the IsoPrime - EA Main Menu Bar, from which further menus can be selected to control the mass spectrometer. For details of menu selection please see previous section.

This section of the manual will therefore give a description of all the menus as they appear on the screen.

Inlet

Not normally applicable to EA.

Mass Spec

This menu contains all the necessary commands to effectively operate the mass spectrometer.

The options are:

Tune Source

This menu item enables adjustment of the source parameters. It opens the 'Tune Source Electronics' dialogue box, which can be moved around the screen if required.

IsoPrime - EA User Manual

- As can be seen the dialogue box controls the following parameters:
- **Accelerating Voltage** between 0 and 5kV
- **Extraction Voltage** between 0 and 100% of the accelerating voltage
- **Half Plate Differential** between -150V and +150V
- **Z Plate Voltage** between -225V and +225V
- **Trap Current** between 0 and 1000 μ A
- **Electron Volts** between 50 and 100 V
- **Ion repeller Voltage** between -15V and +50V
- **Magnet Current** between 0 and 5 Amps

To alter an individual tuning parameter either enter the new value in the entry field next to the source parameter (and click on another box) or use the scroll bar.

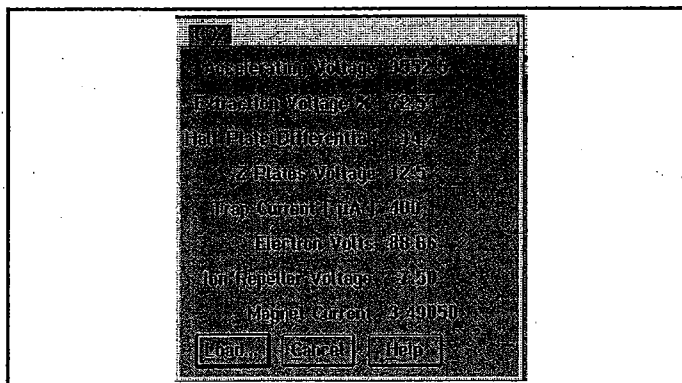

The dialogue box has the following push buttons:

- 'View' allows stored tuning files to be viewed or deleted via the 'View Tuning' dialogue box. This facility therefore allows the parameters to be checked for accuracy and safety prior to loading.

This dialogue box has the following push buttons:

- 'View' loads the source tuning file selected from the list box. This opens the dialogue box below which gives a list of the source parameters for the chosen file.

From here the tuning file can be loaded using the 'Load' push button. The dialogue box can be closed using the 'Cancel' push button or user help can be obtained using the 'Help' push button

IsoPrime - EA User Manual

- **'Cancel'** exits the dialogue box without taking any actions.
- **'Help'** gives information on the operation.
- **'Load'** loads all the voltages and currents indicated by the parameters in this window onto the ion source. Be sure that this action required before the **'Load'** button is clicked!
- **'Load'** opens the **'Load Tuning'** dialogue box, which allows the source tuning files for the various gas species to be loaded (or deleted).

This dialogue box has the following push buttons:

- **'Load'** loads the source tuning file selected from the list box. The tuning parameters in that file are immediately loaded (if unsure then use View first).
- **'Cancel'** exits the dialogue box without taking any actions.
- **'Help'** gives information on the operation.
- **'Delete'** allows the user to delete the source tuning file chosen from the list box. A dialogue box is opened to confirm the deletion of the file
- **'Save'** opens the **'Save Tuning file'** dialogue box, which allows a tuning file that has been changed or a new tuning file to be saved.

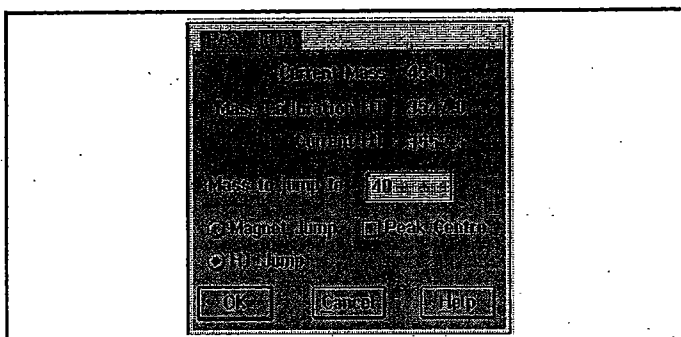

The dialogue box has the following push buttons:

- **'Save'** saves the tuning file under a new file name by typing in a new name in the entry field or can be over written on an existing file name by selecting a name from the list box.
- **'Cancel'** exits the dialogue box without taking any actions.
- **'Help'** gives information on the operation.

- **'Delete'** allows the user to delete the source tuning file chosen from the list box. A dialogue box is opened to confirm the deletion of the file
- **'Cancel'** exits the dialogue box without taking any actions.
- **'Help'** gives information on the operation.

Peak Jump

This command allows the user to position another mass in the central collector by moving the HT voltage or the magnet current. It opens the **'Peak Jump'** dialogue box, which can be moved around the screen if required. Before a peak jump can take place, the **'Current Mass'** mass must be set from **'Tests'**, **'Identify Peak'**. See the section **Identify Peaks** later in this section.

This dialogue box displays the following:

- **'Current Mass'** (the Identified mass which can be seen in the monitor window)
- **'Mass Calibration HT'** (this is the source voltage at which the mass calibration was taken)
- **'Current HT'** (the source voltage, which for an accurate magnet peak jump must be the same as the mass calibration HT).

The new mass to be focused in the axial collector is entered in the **'Mass to jump to'** entry field. The option is then whether to **'Magnet Jump'** or **'HT Jump'** by selecting one of the radio buttons. After peak jumping the software can be asked to perform a peak centre, by selecting the **'Peak Centre'** check box.

The dialogue box has the following push buttons:

- **'OK'** starts the peak jump routine.
- **'Cancel'** exits the dialogue box without taking any actions.
- **'Help'** gives information on the operation.

Source On

This menu option when selected turns **ON** the power to the source electronics. No source potentials are loaded, but the filament is turned on.

Source Off

This menu option when selected turns **OFF** the power to the source electronics.

Enable Hall Probe

This menu option enables the magnet to function with the Hall Probe (i.e. Field Mode), giving a message in the message window 'Hall Probe Enabled'.

Note: This command should be ignored if there is no Hall Probe fitted to the system.

Disable Hall Probe

This menu option disables the Hall Probe (i.e. magnet operating in Current Mode), giving the message 'Hall Probe DISABLED'.

Note: This command should be ignored if there is no Hall Probe fitted to the system.

Penning On

This menu option when selected turns **ON** the Penning Gauge. The command will have no effect if the Penning Gauge is already on.

Penning Off

This menu option when selected turns **OFF** the Penning Gauge. The command will have no effect if the Penning Gauge is already off.

Scan

This menu enables the user to perform all the necessary scan functions required, e.g. HT, magnet etc.

This menu option accesses 'Load Scan Parameter File' list box.

- ## Scan

IsoPrime - EA Menus

The dialogue box will be described in three areas as given below:

'Select scan variable'

- This area contains the following radio buttons that enable the user to choose the X-axis variable to be scanned. (voltage, time or magnet)
- 'Accelerating voltage' allows the amplifier signals to be scanned with respect to the source accelerating voltage, keeping all other parameters at the same conditions.
- 'Time' allows the amplifier signals to be scanned with respect to time (useful when leak checking), keeping all other parameters at the same conditions.
- 'Magnet' allows the amplifier signals to be scanned with respect to the magnet current (or field if the Hall probe is enabled), keeping all other parameters at the same conditions.
- 'Mnemonic' is selected, a source parameter can be scanned by inputting the appropriate mnemonic into the entry field. The mnemonics must be entered as capitals and they are:

| | |
|------|-------------------------|
| EX - | Extraction Voltage |
| HP - | Half Plate Differential |
| ZV - | Z Plate Voltage |
| TR - | Trap Current |
| EV - | Electron Volts |
| IR - | Ion Repeller |

'Select Scan Range'

IsoPrime - EA User Manual

This area controls the X axis variable of the scan. There are entry fields for scan width ('Width'), step size between points ('Step'), and integration time at each point ('Integ Time').

The 'Default Scan' check box is selected (ticked) then the scan range is input in the 'Width' entry field, (this is the total width of the scan, e.g. if when scanning voltage 50V is inputted in the entry field, then the scan will be $\pm 25V$ around the current accelerating voltage). However if the 'Default Scan' check box is not ticked, the 'Width' entry field is no longer accessible. In this case extra entry fields become available 'Min X' and 'Max X', which allow you to select the lower and upper limits of the x values (minimum and maximum to be used).

Notes: If a Time scan is selected, only the 'Max X' entry field is used to enter the duration of the scan in seconds (there is no 'Min X' as time always starts at time zero), and the 'Step' field is used to enter the time step.

If the 'AutoRepeat' check box is selected then the scan will clear at the end of the scan, before starting the scan again (this is particularly useful when peak shaping).

Lower Entry Field (Line Details)

Each line in the bottom part of the dialogue box sets up one trace on the scan (up to a maximum of four).

The fields are:

'Collectors'

Identifies the collector output to plot.

Note: This can be a ratio.

Entries should be made in the exact form shown below

Major

Minor1

Minor2

Minor1/Major

Minor2/Major

There should be no spacing between any of the characters, additionally the first letter of the collector name should be in capital.

- **'Label'**

The text in this field will appear on the screen to label the scan at the right hand edge of the scan window.

- **'y min', 'y max' and '%'**

These 3 fields control the Y-axis scale. The entry fields 'y min' and 'y max' are used to enter specific values (using scientific notation).

By entering a value in the '%' column, the software will automatically scale a ratio or beam intensity within the requested range, according to the intensities measured before starting the scan. **Please note that the entry in the % column to define the scale for a ratio is in units of δ**

- **'Colour' and 'Graph'**

The **'Colour'** entry fields determine the colour in which a line is drawn in the Scan Display Window. A number indicates the colour. The numbers are the same as used in screen messages, the main colours being:

| | | | | | |
|----|------------|---|-----------|----|------------|
| -2 | White | 4 | Green | 10 | Dark red |
| -1 | Black | 5 | Cyan | 11 | Dark Pink |
| 0 | Background | 6 | Yellow | 12 | Dark Green |
| 1 | Blue | 7 | Neutral | 13 | Dark Cyan |
| 2 | Red | 8 | Dark Grey | 14 | Brown |
| 3 | Pink | 9 | Dark blue | 15 | Pale Grey |

The **'Graph'** entry fields allow a number of separate graphs to appear in the Scan Display Window at the same time. You may have up to 4 graphs (entered 0 - 3 in the entry field). If you are plotting beam intensities it may be best to show these all on the same graph (in which case use the same number), to illustrate beam coincidence, but, for example, a ratio is best shown on its own graph, because of the different Y scale.

The Scan Setup dialogue box also has the following push buttons:

- **'Delete Line'** deletes a selected line from the lower entry details (collector details). The line is selected by selecting any of the entry fields on the line. A confirmation dialogue box is accessed to safeguard against accidental deletion.
- **'Load'** accesses **'Load Scan Parameter File'** list box, which enables you to select a scan parameter file to be loaded and has the following push buttons:

This dialogue box has the following push buttons:

- **'Load'** loads the **'Scan Setup'** dialogue box for the file chosen from the list box.
- **'Cancel'** exits the dialogue box without taking any actions.
- **'Help'** gives information on the operation.
- **'Delete'** allows the user to delete the scan parameter file chosen from the list box. A dialogue box is opened to confirm you wish to delete the file ('Yes' or 'No' push buttons).

- 'Save' saves the scan setup file in the existing Scan Parameter File (overwrites the file called up).
- 'Save As' selects the 'Save Scan Parameter File' dialogue box which enables new scan files to be saved and has the following push buttons:

This dialogue box has the following push buttons:

- 'Save' saves the scan setup file in a scan parameter file chosen from the list box or under a new name entered in the entry field.
- 'Cancel' exits the dialogue box without taking any actions.
- 'Help' gives information on the operation.
- 'Delete' allows the user to delete the scan parameter file chosen from the list box. A dialogue box is opened to confirm you wish to delete the file ('Yes' or 'No' push buttons).

Run Scan Param File

This menu option accesses 'Run Scan Parameter File' list box.

The list box enables you to select a scan parameter file to be run and has the following push buttons:

- 'Run' runs the selected scan parameter file from the list box.
- 'Cancel' exits the dialogue box without taking any actions.
- 'Help' gives information on the operation.
- 'Delete' allows the user to delete the scan parameter file chosen from the list box. A dialogue box is opened to confirm you wish to delete the file ('Yes' or 'No' push buttons).

Note: For details of the Scan Window see below.

Scan Display Window

When you start a scan, the 'Scan Display Window' appears in the middle of your screen. It can be resized and positioned to suit your own requirements. The window has its own Menu Bar and will show a graph for each plot you have set up in the 'Scan Setup' dialogue box.

Scan Display Window Menu Bar

The 'Scan Display Window' has the following options on its menu bar:

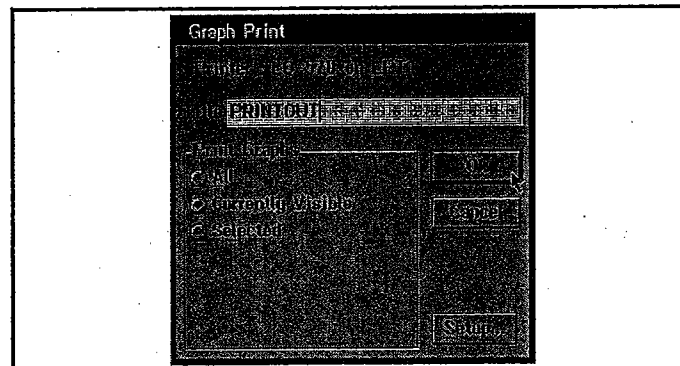

Graph

This menu option has the following commands:

- 'Print'

This menu option opens the 'Graph Print' dialogue box.

This dialogue box allows you to give the print out a title in the 'Title' entry field and to select the graphs to be printed using the radio buttons in the 'Print Graphs' section. The radio buttons are:

IsoPrime - EA User Manual

- 'All' when selected prints all the graphs selected from scan.
- 'Currently Visible' when selected will print all the graphs in the scan window.
- 'Selected' when selected opens a list box from which graphs to be printed can be selected, by clicking on the required graph title.

The dialogue box also has the following push buttons:

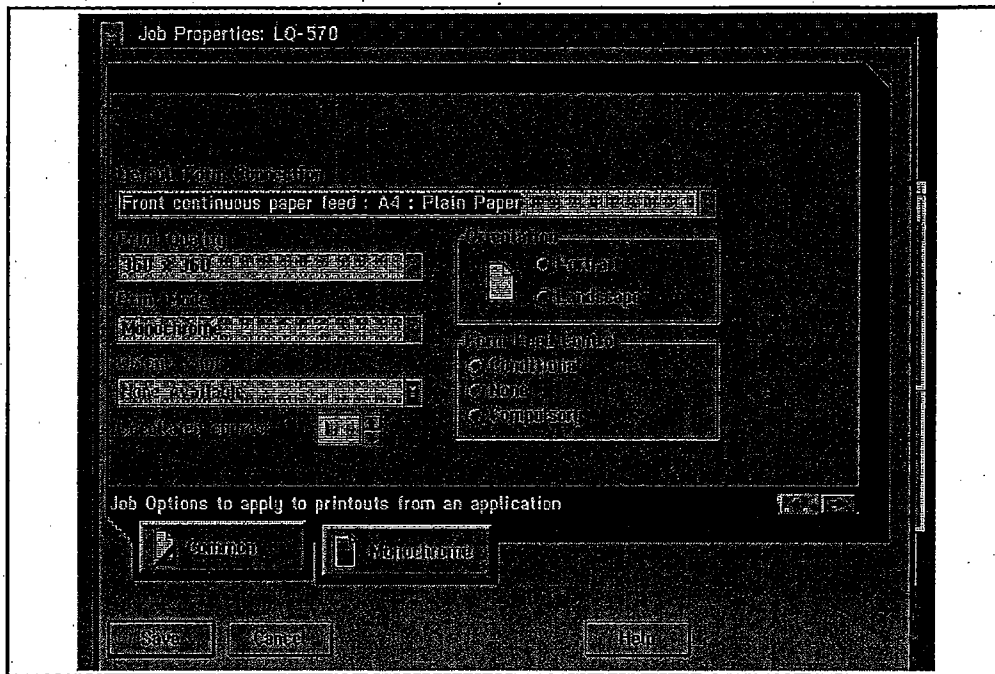

- 'OK' will then start the print out.
 - 'Cancel' push button exits the dialogue box without taking any actions.
 - 'Setup' will open the 'Select Printer' dialogue box as described below.
- 'Print Setup'

This menu option opens the 'Select Printer' dialogue box. This allows the type of printer to be printed to, to be chosen. A list of available printers appears in the list box

The dialogue box has the following push buttons:

- 'OK' will specify the printer selected in the list box as the preferred printer until changed (by selecting a different printer).
- 'Cancel' push button exits the dialogue box without taking any actions.
- 'Setup' will open the selected printers 'Job Properties' dialogue box, from which the print out details can be edited. For details of the 'Job Properties' dialogue box see OS/2 Manual.

- 'Help' push button gives information on the operation.

Cursor

This menu controls the behaviour of the mouse pointer within the graphical display area. The commands all act with a 'Menu Tick' function and are:

- 'Zoom In'
When chosen, the mouse cursor becomes a magnifying glass symbol. By dragging the magnifying glass over an area of the scan you can examine it in greater detail. If required you can 'Zoom In' in several stages.
- 'Zoom Out'
By clicking on a 'Zoom In' graph after selecting 'Zoom Out', the plot will go back to the size previously displayed prior to a 'Zoom In', this can be done several times until the graph is back to full scale use.
- 'Full Size'
This will return a graph to full scale, simply by clicking on the plot.

- 'Pan'

This is greyed out and has no function.

- 'Drag'

When Drag is selected, you can use the mouse to pick up and move the vertical cursor line used to show the current voltage. This is useful if a new analysis position is required on the flat top.

- 'Raw Data'

Raw Data mode provides an additional vertical cursor, which can be used in conjunction with the drag facility to examine the raw scan data in a small window at the bottom left of the screen. Only those lines ticked in the lines menu (see below) have their raw data displayed.

- 'Link Zoom'

When selected, the mouse symbol becomes 2 linked loops. Using this, you can link the x scale of two graphs by clicking on them in turn. After adjusting the horizontal scale on a particular graph (graph A), in order to copy this scale onto a second graph (graph B) then:

1. Select link zoom
2. Click on graph A
3. Click on graph B

Lines

This menu contains a list of the lines available for display. The text in the menu is the label you have entered in the Scan Setup dialogue box. By ticking lines on or off from this menu you can simplify the display window.

Window

The commands all act with a 'Menu Tick' function and are:

- 'Cascade'

This default setting will arrange multiple graphs one above the other in the display window (i.e. one column).

- 'Tile'

This option will arrange graphs side by side, as well as above each other (i.e. two or more columns).

Scan

The commands are:

- **'Centre'**
This command automatically centres the voltage cursor (peak centre).
- **'Quality'**
This command performs a peak quality check and sends the results to the printer, (see section on peak quality).
- **'Repeat'**
This repeats the scan once, if auto repeat has not been set.
- **'Halt'**
This command halts a scan while in progress.

Tests

This menu contains a set of commands used to check the status of the instrument, as well as being required for day to day running.

The menu options are:

Peak Quality

This menu option provides a quantitative measurement of the quality of your peak shapes, in terms of flatness, symmetry and resolution. When the **'Peak Quality'** command is chosen a peak centre is carried out (as above) and the resolution, symmetry, and peak top flatness are measured of any peak found within the range of the centre scan, these are then output to the printer.

Note: If the peak quality of all the collectors are required then the other beams need to be added to the centre scan procedure.

Identify Peak

This opens 'Identify Axial Peak' dialogue box, which allows you to identify the mass in the axial collector (i.e. the mass presently in the axial collector or the mass you are going to move to the axial collector).

This is particularly important as this sets the 'beam mask', which selects the collector array into which the beams are measured (see section on the IsoPrime collector array).

Examples of the 'Beam Mask' are given below:

If mass 45 is selected (measuring CO₂) then the following mask is used;

| | |
|------------------|-----------------|
| Beam 1 (mass 44) | Low 1 Collector |
| Beam 2 (mass 45) | Axial Collector |
| Beam 3 (mass 46) | High Collector |

If mass 29 is selected (measuring N₂) then the following mask is used;

| | |
|------------------|-----------------|
| Beam 1 (mass 28) | Low 1 Collector |
| Beam 2 (mass 29) | Axial Collector |
| Beam 3 (mass 30) | High Collector |

The 'Identify Axial Peak' dialogue box displays the 'Current Axial Mass' (also shown in the monitor window) which is the mass, the mass spectrometer accepts as the axial mass. However, if the magnet current or accelerating voltage has been moved by the user then a new axial mass must be identified in the 'New Mass Identity' entry field.

Note: Always identify the current axial mass when changing gas species.

The dialogue box has the following push buttons:

- 'OK' enters the 'New Mass Identity' given in the entry field and exits the dialogue box.
- 'Cancel' exits the dialogue box without taking any actions.
- 'Help' gives information on the operation.

Mass Calibration

This menu option opens the 'Mass Calibration Points Entry' dialogue box, which enables the mass spectrometer to be mass calibrated (i.e. the values obtained for mass value against magnet current are input into the computer in this dialogue box).

The dialogue box contains a list box with 2 entry fields on each line. The entry fields expect the 'Accurate Mass' and the 'Magnet Current' at which the mass is found.

Note: The list box has no limit to the number of peaks and the greater the number of peaks input the more accurate the mass calibration will be.

The dialogue box also has the following push buttons:

- 'Clear' removes all the entries from the list box (i.e. all the mass and magnet current data).
- 'Calculate' performs a line fit on the data points entered in the list box, which will be used to fill in the gaps in the data. This must be selected prior to entering the data.
- 'Sort' puts the entries in the list box above in mass order, with the lowest mass number at the top.
- 'Enter' saves the data to disc and exits the dialogue box.

Peak Centre

This menu option will automatically set the accelerating voltage to focus (centre) the mass in the axial collector. This is accomplished using the scan procedure file 'Centre' to scan the axial collector. If a peak is found within the scan range then the accelerating voltage is set to the peaks central value (marked with a broken vertical line). The peak shape is displayed, and may be printed out if desired, the window will stay open until closed by the operator.

Analysis

The analysis menu provides the facility for the acquisition of data through the development of different methods for each type of analyses required. A method contains all the parameters required to acquire the data, and to perform an initial data processing (AutoDP) on the acquired data. The User of the instrument defines the parameters within the Method. When a sample is analysed, the method relevant to that sample is loaded into the software. Analyses can be performed in one of two modes:

- **'Single Run'** mode for analysis of single samples
- **'Autorun'** mode for batch analysis of a number of samples.

The Analysis Menu is shown below:

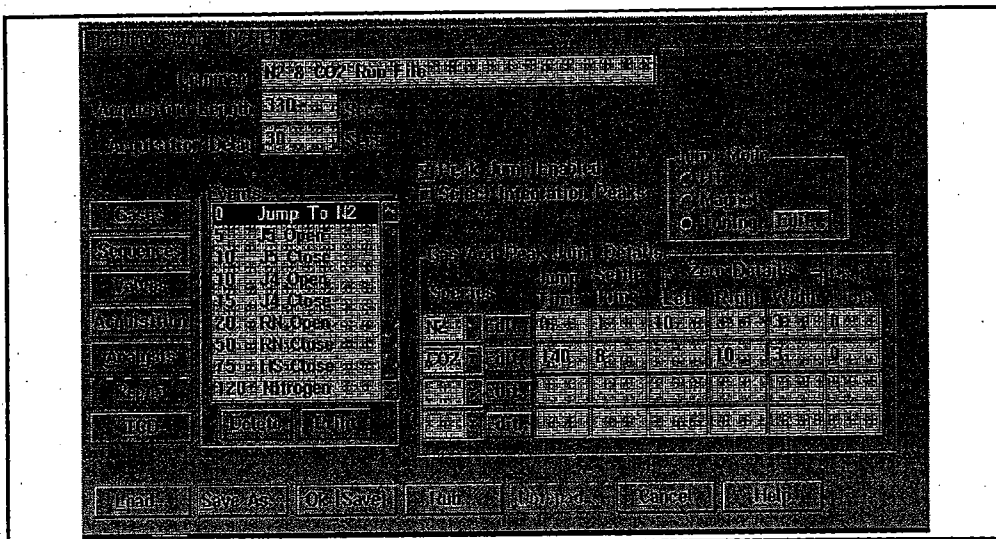

- The **'Method Setup'** option accesses the Method Setup dialogue box allowing generation and modification of methods.
- The **'Single Run'** option accesses the 'Single Run' dialogue box allowing analysis of single samples.
- The **'Edit Autorun'** option accesses a further menu in which facilities for batch analysis are available.
- The **'Autorun Stop'** facility halts any current batch analysis at the end of the current acquisition.
- The **'Parameter File Edit'** option accesses the Parameter file list, through which a series of instrument constants and settings can be accessed. The parameter files for the EA software are described later in this chapter
- The **'Batch DP'** option is used a lot in the EA software. The DP software is described in the next chapter of this manual. Worked examples for Manual data processing are also described in Chapter 6

The following sections describe each of the parameters and options encountered in the Analysis Menu. Guidance on how to use the Analysis Menu to acquire data is described in Chapter 6

Method Setup

Select 'Method Setup' option to access the 'Method Setup' dialogue box. The Method Setup dialogue box defaults to reveal the Gases overlay when the Method Setup dialogue box is accessed.

IsoPrime - EA User Manual

- The vertical set of Push buttons on the left-hand side of the dialogue box.

In this set there are 7 Push buttons:

Gases
Sequences
Valves
Acquisition
Analysis
Report
TCD

These Push buttons will call the set of parameters associated with their respective labels. For example the Push button labelled 'Gases' will call all the parameters which are associated with the information required to analyse a particular gas species (i.e. the reference gas calibration data, whether peak jumping will be required during the data acquisition, and if so, which gas to peak jump to etc.)

The set of parameters called by a particular push button will appear on the overlay area on the right hand side of the dialogue box.

- The 'Events' window.

The Events window lists all the events occurring during data acquisition using the currently loaded method. Individual Events can be highlighted to reveal the appropriate programming overlay. For example highlighting the '0 Jump To CO₂' event will reveal the Gases overlay. Individual Events can be deleted from the Events List using the 'Delete' push button. The Events List can be printed to hardcopy by clicking the 'Print' push button.

- The Jump mode and Peak jump options above the overlay area. These options allow the operator to select which gas species are to be analysed and define how the mass spectrometer automatically retunes the source to the different gas species.

- The overlay area on the right hand side of the 'Events' window.

This area is reserved for the set of parameters called by a particular push button on the left-hand side of the dialogue box. The Gas overlay appears when the 'Gases' push button is depressed, the Sequences overlay replaces it if the 'Sequences' push button is pressed in and so forth for the remaining 5 overlays.

The software remembers the last overlay used. On requesting 'Method Setup', therefore the last used overlay will appear. If none were called since the program was booted up, then the gas overlay appears by default.

- The horizontal set of Push buttons on the lower part of the dialogue box.

- 'Load' loads an existing method into the Method Setup facility. The Load Button reveals the 'Load Method File' list box. To load a method, either type in the name of the desired method in the 'Filename' entry field, or highlight the desired method name in the Filename list using the mouse cursor.
- 'Save As' creates a method under a new file name. The 'Save Method File As' dialogue box is revealed.. To generate a new method, alter an existing method to the desired configuration and save it under a new name by typing a new filename into the 'Filename' entry

IsoPrime - EA User Manual

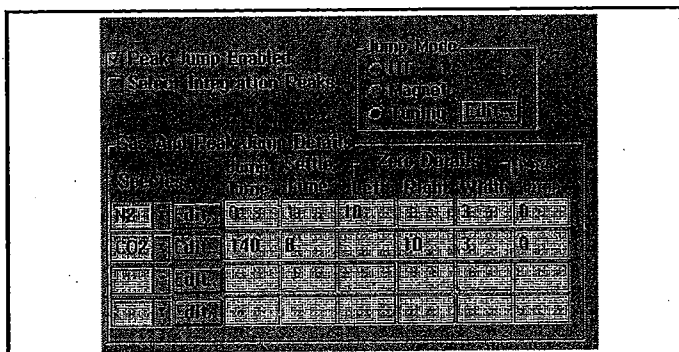

- **'OK (Save)'** saves the current settings in the Method Setup systems under the current filename.
- **'Run'** accesses the **'Single Run'** dialogue box for performing a single analysis.
- **'Notepad' ****** This is not implemented on this version of the software ****
- **'Cancel'** closes the **'Method Setup'** dialogue box without saving any alterations.
- **'Help'** accesses the help facility associated with the Method Setup dialogue box, and with the currently selected Method Setup panel.
- **'Acquisition' ****** This is not implemented on this version of the software ****
- **'Analysis'** reveals the Analysis overlay and gives access to all the analysis parameters that will be used during the automatic data processing at the end of the data acquisition cycle.
- **'Report' ****** This is not implemented on this version of the software ****
- **'TCD'** reveals the TCD panel, providing facilities for limited integration if peaks on the TCD trace.

Gases Overlay

Gases' reveals the Gases, Peak Jump and the zero details panel.

Clicking on the **'Gases'** push button, or on a **'Jump To'** entry in the Events List calls the Gases overlay.

The gases overlay is shown in the figure below. The overlay allows selection of gas species to be analysed, and specifies the points at which instrument zeros are to be measured. Note, in this example where peak jumping is enabled only one zero position for both nitrogen and carbon is selected. For nitrogen it is generally set to the left of the reference pulse and for carbon to the right of the reference pulse. A maximum of two zero positions is allowed for any gas species.

The overlay has the following features:

- **'Peak Jump Enabled'** tick box. This facility is very often used with the IsoPrime EA. The selection of this box expands the gases overlay to allow for up to 4 gas species to be analysed.

- **'Select Peaks for Integration'** tick box. This facility is not normally used with the IsoPrime-EA and the box should not be ticked.

Gas **'Species'** combo box. This facility specifies the gas species to be analysed during acquisition. Click on the right-hand downward-pointing arrow to reveal the gas species list. Double - click on the choice of gas to be analysed. The isotopic composition of the relevant reference gas is entered in the **'Gas Parameters'** dialogue box, accessed by clicking on the right-hand **'Edit'** push button. The **'Gas Parameters'** dialogue box enables entry of the details of each reference gas. The Gas Parameters dialogue box for CO₂ is shown in the figure below

This dialogue box has the following features:

- **'Comment'** Entry Field: Allows entry of up to 32 text characters forming a comment on the reference gas.
- **'Delta C13 Per Mil'** Entry Field: Contains the Craig - corrected $\delta^{13}\text{C}$ (‰ PDB) value for the reference CO₂.
- **'Delta O18 Per Mil'** Entry Field: Contains the Craig - corrected $\delta^{18}\text{O}$ (‰ PDB) value for the reference CO₂.
- **'With Respect To'** Combo Box: This facility contains a list of all the international reference standards, for example PDB, Air, CDT etc. Click on the right-hand, downward-pointing arrow to reveal the list, then double click on the choice of international standard.
- **'Ok'** push button: Saves any modifications and closes Gas Parameters dialogue box.
- **'Cancel'** push button: Closes the dialogue box without saving any changes.
- **'Help'** accesses the help facility associated with the dialogue box.
- **'Zero Details Entry Field' (Left and Right)**: Specify here the time, in seconds, after the start (left value) and before the end (right value) of acquisition at which instrument zeros will be measured. There are 10 integration points per second.
- **'Zero Details Entry Field (Width)'**: Enter here the number of seconds used for the measurement of the instrument zeros.
- **'Peak Time'**: This facility is greyed out, therefore not accessible, unless the **'Select Integration Peak'** tick box has been ticked. This facility is not normally used with the IsoPrime-EA.

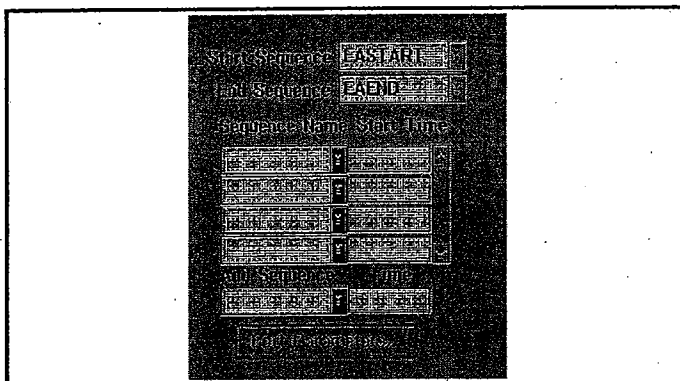

Jump Mode

The mass spectrometer can essentially jump between different masses in by three distinct methods.

- **HT:** Using the general mass spec equation of Section 3, the software recalculates the new acceleration voltage for the next mass to be analysed.
- **Magnet:** The software selects the value of the new magnet current as specified in the mass calibration table which sits in the desktop under Tests.
- **Tuning:** Selecting the activated **EDIT** button accesses the load tuning file window which allows the user to define which tuning file is reloaded when jumping to a particular species. Tick the gas option and select which tuning file to associate with it using the combo box.

Sequences Overlay

'Sequences' calls the sequence overlay containing details of start and stop sequences, and allows entry of parameters used in extra, user-defined sequences. It is shown in the figure below.

This overlay has the following features:

- **'Start Sequence' Combo Box.** Specifies the start sequence to activate the acquisition process. Click on the right-hand, downward -pointing arrow to reveal the list of available sequences. Double - click on the desired sequence for starting the acquisition procedure.
- **'End Sequence' Combo Box.** Specifies the end sequence, which terminates the acquisition process. Click on the right-hand, downward-pointing arrow to reveal the list of available sequences. Double - click on the desired sequence for ending the acquisition procedure.
- **'Sequence Name'** If the particular application requires hardware that is additional to the standard hardware supplied with the IsoPrime-EA, then this hardware may be controlled through the use of user specified sequences. The names of these sequences are then declared in these fields. The sequences can then be activated before, during or after an acquisition by declaring the Start Time of each of these additional sequences in the adjacent field set.

IsoPrime - EA User Manual

- **'Start Time'** The Start time of any additional user defined sequence is declared in this list, adjacent to the name of the corresponding sequence.
- **'Add Sequence'** Combo Box. Additional sequences are added to the existing list, using this entry field.
- **'Time'** The time for any additional sequence, to be added to the existing list is declared in this field.

Valves Overlay

'Valves' calls the Valves overlay allowing programming of all the valve actions required during an acquisition

Clicking on the **'Valves'** push button, or on a valve action in the Events List, accesses the Valves overlay. The timing of all the valve actions in a method are controlled through the Valve Panel.

This panel has the following features:

- **'Mnemonic'** Entry Field. Contains the mnemonic for any valve for which timed actions are to be entered. The standard software recognises RG for the CO₂ Reference Gas Valve, RN for the N₂ Reference gas valve, and HS for the Heart Split Valve. Enter the appropriate mnemonic to edit the desired valve timings, then press return.

Note that the HS valve defined as a sample valve does not control an actual valve in this application. It is used solely for the purpose of defining a window within which the program will search for sample peaks to integrate. The user **must** ensure that any sample peaks to be integrated are **wholly** contained within this window. Particular care must be taken when defining the right limit for the integration window to ensure that any peak tailing, if present, is included within the integration window. Integration stops at the end of the integration window, it does not stop at the end of a peak, unless this is contained within the integration window.

- **'Pulse Width'** Entry Field. Contains the width, in seconds, of any reference gas pulse. This entry field remains greyed out when a mnemonic for a non-reference gas valve is entered in the Mnemonic Entry Field.
- **'Transport Time'** Entry Field. This contains the time delay, in seconds, between the valve action and the effect observed in the mass spectrometer. For example the time delay between opening the RG valve and the reference gas beams appearing in the collectors.

IsoPrime - EA User Manual

- **'Valve Type' Radio Buttons.** Specifies which type of valve (Reference, Sample or Prep) for each mnemonic. Thus the HS valve is specified as a Sample valve, RG as a reference valve. Valves incorporated into custom-built preparation systems can be entered as Prep valves.
- **'Valve Timings' Window.** The Valve Timings Window lists the action times for the valve mnemonic in the Mnemonic Entry Field. To access the Valve timings for a particular valve enter the desired mnemonic in the Mnemonic Entry Field, or double click on a suitable valve action in the Events list.
 - **'Valve Timings Open'** lists the time(s) in seconds at which the specified valve will be open. The vertical scroll bar can be used to view the entire list.
 - **'Valve Timings Close'** lists the time(s) in seconds at which the specified valve will be closed. For reference valve timings this will be automatically calculated by adding the value in the Pulse Width Entry Field to the corresponding Valve Open time. For Sample and Prep valve times the operator must determine the closure times. The vertical scroll bar can be used to view the entire list.

Acquisition Overlay

Clicking on the 'Acquisition' push button calls the Acquisition overlay. The Acquisition Panel provides the facility to customise the data acquisition window and the final default print report.

This panel has the following features:

- **'Collectors to Acquire'** combo box is used to select the collectors and detectors used for the acquisition. In the EA software, for CO₂ and N₂ analyses, this will normally include Major, Minor1, Minor2 and TCD
- **'Traces to Display'** panel. **** This facility is greyed out and is not accessible ****
- **'Print Graph'** Tick Box. If the user requires to print the Mass Spectrometer trace acquired during an acquisition, on the final default report, then a tick should be entered in this field.

- **'Print Results' Tick Box.** If the user requires to print the results of an analysis on the default run report, then a tick should be entered in this field.

This facility is particularly useful when performing a Batch analysis. If the field is left unticked, then the results from each single analysis within the batch will not be printed at the end of each analysis but will be delayed until the batch summary report is printed. The final batch report has a much more condensed format thus avoiding large quantities of printer paper being used in the event that all intermediate results are not required.

Analysis overlay

The Analysis overlay is called by clicking on the Analysis push button. The parameters in the Analysis Panel control the protocols for the automatic data processing (AutoDP), occurring directly after the data acquisition process. The parameters can be modified in the manual data processing (DP) software. The parameters are divided between two windows. The secondary, or extended parameters, are called by clicking on the Extended Parameters button. The Extended Parameters are described in a later section.

This panel has the following features:

There are two parameters that control the size limits for peak integration during data processing. Below these limits peaks will not be integrated, the limits are set in the entry fields below:

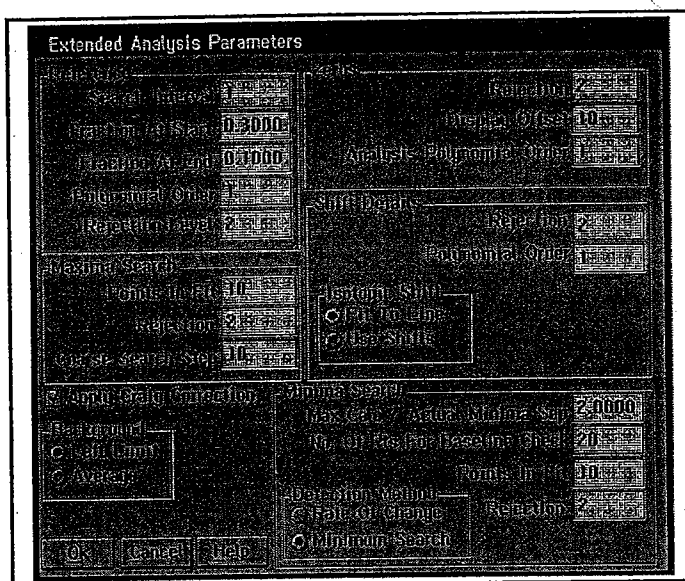

- **'Peak to Zero Line' Entry Field.** The value entered here (in Amps) represents the height threshold, measured from the Major zero line to the peak apex, below which peaks are not integrated.
- **'Peak to Baseline' Entry Field.** The value entered here (in Amps) represents the height threshold, measured from peak baseline to apex, below which peaks are not integrated.
- **'Bknd/Pk Height'.** The value entered here represents the height of the background at the left limit of a sample peak, expressed as a percentage of the sample peak height. Peaks, for which this percentage is below that defined, will not be background subtracted. They will however be zero subtracted. Peaks for which this percentage is greater than that defined, will be background subtracted in addition to the zero subtraction.

This feature allows background subtraction to be performed on an entire mass chromatogram, yet selecting peaks automatically along this chromatogram which are very large compared to the background and for which background subtraction is not necessary.

- **'Multiplet Analysis'** Parameters control the protocols for recognising doublets and multiplets occurring on complex chromatograms. Where a multiplet is recognised, a different method of peak integration is employed.
 - **'Multiplet Offset' (Amps)** Entry Field. This provides a facility for identifying those doublets, or multiplets containing significantly overlapping peaks. The value entered here (in Amps) represents a height threshold, measured from the multiplet baseline to doublet minima, above which the peaks will be integrated using the doublet method.
 - **'Maximum Separation for Doublet' (seconds)** Entry Field. This parameter helps identify those peaks that are sufficiently close to be considered a doublet or multiplet series. The value entered here (in seconds) represents the interval between peaks within which the peak pair is classified as a doublet, and integrated accordingly. The interval is measured from one peak right limit to the next peak left limit.
 - **'Force Horizontal'** tick box. When selected the multiplet baseline is drawn as horizontal, rather than as a sloping fit between the left and right limits for this multiplet. The lowest point is used to draw this line.
- **'Background Subtraction'** parameters influence the protocols for controlling the background correction algorithms.
 - **'Bknd Subtraction'** tick box activates the background subtraction process during AutoDP.
 - **'Fit Type'** radio button selected specifies the desired type of line, either polynomial curve or spline function, for the background correction protocols. The spline function is not yet available.
 - **Major Degree and Rejection: ****** This facility is greyed out and is not accessible ****
 - **2/1 Degree and Rejection:** the order of the polynomial curve used for modelling the 2/1 ratio trace for background subtraction is entered in the Degree entry field. The curve is drawn through the background points on the 2/1 ratio trace. Those points falling more than the number of standard deviations specified in the Rejection entry field from the line will be disabled. Disabled points will be marked in red on the graphics.

Clicking on the **Extended Parameters** button in the **Analysis Overlay** calls the **Extended Analysis Parameters** dialogue box.

- **'Reference' Parameters** control the protocols or the search and integration of reference peaks.

- Page 53

- 'Fraction at Start' entry field is the portion at the start of the reference peak which is disregarded during integration of the reference peak
- 'Fraction at End' entry field is the portion at the end of the reference peak which is disregarded during integration of the reference peak.
- 'Polynomial' entry field. The order of the curve drawn through the reference ratio points (both 2/1 and 3/1 ratios) is specified in this entry field. It is recommended that order 1 is always used.

A polynomial defines a mathematical curve. The number of turning points for this curve is defined by the order of the polynomial. Examples of general shapes for orders 0 to 6 are given below

- 'Rejection Level' entry field specifies the rejection level, in standard deviations, outside which individual reference peaks are not used. Disabled peaks are coloured red.
- 'Maxima Search' parameters influence the protocols used for finding the maxima of each integrated sample peak.
 - 'Points in Fit' entry field specifies the number of readings used in drawing the polynomial curve for determining the peak maxima.
 - 'Rejection' entry field specifies the rejection level, in standard deviations, outside which individual maxima-search points are not used.

- **'Coarse Search Step'** entry field specifies the interval (i.e. the number of scans) used in the coarse-search step of finding the sample peaks. Note that the scanning rate is 10 per second, therefore an entry of 10 would result in a coarse search step of 1 second along the chromatogram.
- **'Minima Search'** analysis parameters influence the protocols for accurately finding the left and right limits of each sample peak. The protocol of determining whether a sloping or horizontal baseline fit should be used is also controlled here.
 - **'Detection Method'** radio buttons specify which method is used for detecting the peak minima:
 - **'Rate of change'**. **** This facility is greyed out and is not accessible ****
 - **'Minimum Search'**. The peak limit is detected at the lowest measured reading around the peak maximum.
 - **'Max Calc/Actual Minima Sep'** entry field specifies the limit, in seconds, between the measured peak minimum and the minimum calculated using the polynomial curve method. If the difference is within the specified limit, then the polynomial minimum is used, otherwise the measured minima is used.
 - **'No of Points for Baseline Check'** entry field specifies the number of scans to the left of the peak minima which are analysed to determine whether the peak baseline cuts the Major Beam trace. If the major is cut, then a horizontal baseline fit is used.
 - **'Points in Fit'** entry field specifies the number of points taken for second order polynomial fit to find the minimum i.e. start at integration limit.
 - **'Rejection'** entry field specifies the rejection level, in standard deviations, outside which individual minima-search points are disabled.
- **'Zeros'** parameters control the drawing of the zero subtraction line, and the performance of the display zero. The Positions of the zero lines are specified in the Gases Panel.
 - **'Rejection'** entry field specifies the rejection level, in standard deviations, outside which individual zero points are disabled.
 - **'Display Offset'** entry field specifies the position of the zero measurements, in scans after the start of acquisition, taken in order to plot accurately the ratio traces during data acquisition.
 - **'Analysis Polynomial Order'** entry field specifies the order of the polynomial curve drawn through the zero analysis points. A first order polynomial should always be used.
- **'Shift Details'** parameters allow selection of the method for compensating for the Isotopic Shift between the heavy and light isotope - rich species:
 - **'Isotopic Shift'** radio buttons:
 - **'Use Shifts'** Radio Button: the isotopic shift values of the individual peaks are used to calculate the δ values of the particular sample peaks.

IsoPrime - EA User Manual

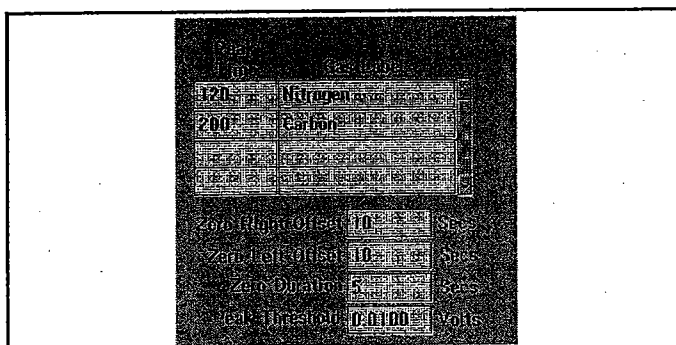

- **'Fit to Line' Radio Button:** the individual Isotopic Shift values are plotted as a function of time, and a best fit polynomial drawn through them. The values used in the isotopic calculations are then extrapolated from the best fit line.
- **'Rejection' entry field** specifies the rejection level, in standard deviations, outside which individual isotopic shift values are disabled during calculation of the Isotopic Shift line.
- **'Polynomial Order' entry field** specifies the order of the polynomial curve used in the calculation of the Isotopic Shift line. A first order polynomial should always be used.
- **'Apply Craig Correction' tick box** enables the application of the Craig correction during $\delta^{13}\text{C}$ (and $\delta^{18}\text{O}$) calculation.
- **'Background' radio buttons:**
 - **'Left Limit' Radio Button:** specifies that the automatic background points selected during AutoDP are positioned at the left limits of the integrated sample peaks
 - **'Average' Radio Button:** specifies that the automatic background points selected during AutoDP are an average of the left and right peak limits of the integrated sample peaks, and positioned at the left limits of the sample peak.
- **'OK' push button** saves any alterations and closes the Extended Analysis Parameters dialogue box.
- **'Cancel' push button** closes the Extended Analysis Parameters dialogue box without saving any changes
- **'Help' push button** accesses the help facility associated with the Extended Analysis Parameters.

Report Overlay

**** This facility is greyed out and is not accessible ****

TCD Overlay

This facility provides the instructions required for the integration of sample peaks acquired by the TCD

The panel has the following features:

- **'Peak Time'** entry field list specifies the approximate retention times, in seconds, of those peaks to be integrated.
- **'Species Label'** entry field list enter the desired label for each peak to appear on the results printout.
- **'Zero Right Offset'** entry field enter the time, in seconds prior to the end of acquisition, at which the right TCD zero measurement will be taken
- **'Zero Left Offset'** entry field enter the delay, in seconds after the start of acquisition, after which the left TCD zero measurement will be taken.
- **'Zero Duration'** entry field enter the time period, in seconds, over which the left and right TCD zeros will be measured.
- **'Peak Threshold'** entry field enter the peak height threshold value, in volts, below which the specified TCD peak will not be integrated.

Analysis

Single Run

The Single Run Option provides the facility for the collection of data from individually performed sample analyses. Selecting this menu option opens the 'Single Run' dialogue box.

This dialogue box has the following features:

- **'Sample Details' panel**
The details of the sample are entered into the appropriate entry field.
- **'Name'** entry field provides 32 characters for recording the full name of the sample. This name is not used for data storage, but appears on the results printout.

IsoPrime - EA User Manual

- **'ID'** entry field provides 32 characters for further identification of the sample, for example the number of a repeat analysis. The ID entry is printed on the results printout.
- **'Injection Size' (mg)** entry field enters the amount of sample to be injected into the elemental analyser. This is used for the calculations of the elemental composition of the sample. An accurate entry of the sample weight must therefore be made for the final calculation to yield an accurate evaluation of the sample elemental composition.
- **'Position'** entry field specifies the position of the sample on the sample carousel. This may be left blank as the entry is used solely for information purpose.
- **'Run Details' panel**

This panel has the following features:
- **'Comment'** entry field provides 200 characters of space for recording specific information about the Single Acquisition, for example EA conditions etc.
- **'Method'** combo box facilitates selection of the method to be used for the Single Acquisition. Click on the right-hand, downward pointing arrow to reveal the list of available methods.
- **'Save Data to Named File'** tick box when selected, the data and AutoDP parameter under a file name and folder specified in the Folder and Filename Entry Fields. When the tick box is not selected, the data is saved under a TEMP filename in a TEMP folder.
- **'Folder'** entry field provides 8 characters to specify the name of the Folder in which the data file will be stored.
- **'Filename'** entry field provides 5 characters for naming the file in which the data will be stored.
- **'Data Logger' panel**

This facility allows transfer of data into spreadsheets.
- **'Enabled'** tick box when activated the appropriate AutoDP data will be stored in a text file (.txt).
- **'Edit'** push button accesses the Data Logger dialogue box.
- **'Run' push button**

Clicking on the run button initiates the data acquisition process, and closes the Single Run dialogue box.
- **'Cancel' push button**

Closes the Single Run dialogue box without initiating the data acquisition process.
- **'Help' push button**

Accesses the help facility associated with the Single Run Dialogue Box.

Edit Autorun →

The 'Edit Autorun' option accesses the Edit AutoRun cascade menu that provides the facility for the setup and execution of batch analyses. Batch analyses are performed in 'AutoRuns'. The cascade menu is accessed by clicking on the right-pointing arrow in the Edit Autorun option, and is shown in the figure below.

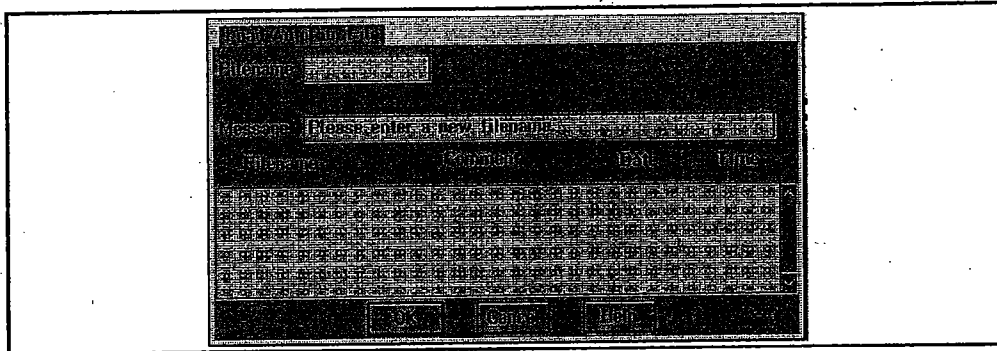

This menu option allows for the following sub-menus to be selected by the sub-menu arrow:

- **'New'** option allows setting up of new autoruns via the Autorun Batch Dialogue box.
- **'Prepared'** option allows access to details of AutoRuns that have been prepared, but have not been executed.
- **'Run'** option allows review of the details of autoruns that have been executed.
- **'Running'** option accesses details of an autorun currently being performed. When no autorun is being performed this option is inactive and appears 'greyed out'.
- **'Interrupted'** option accesses details of any autoruns that have been interrupted (temporarily halted). When no autorun has been interrupted this option is inactive and appears 'greyed out'.

'Load AutoRun File' dialog box

The details of each autorun are stored as an autorun file. When an option in the Edit Autorun cascade menu is selected, the Load AutoRun File dialogue box appears.

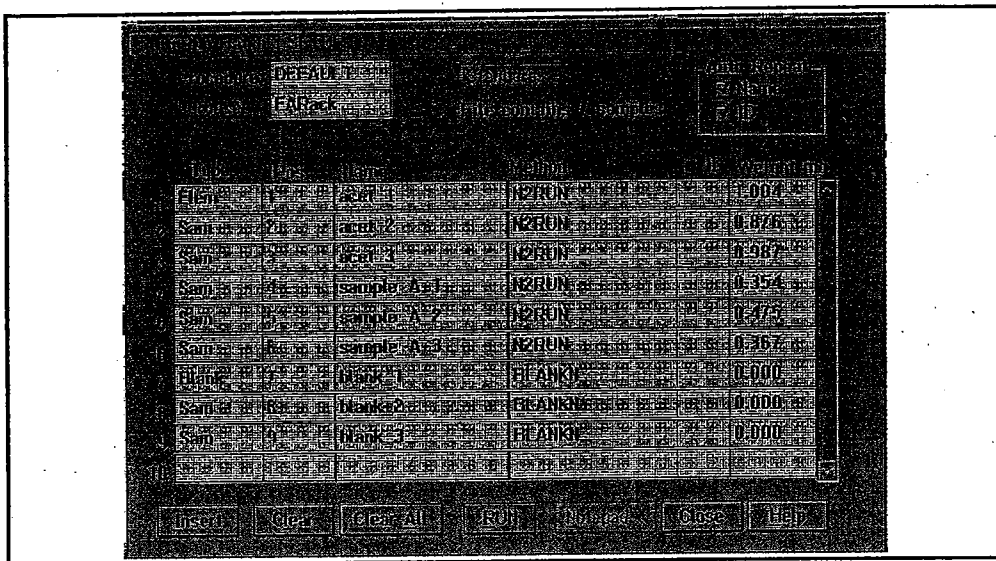

This dialogue box display has the following possibilities:

- When 'New' is selected, a list of all autorun titles is displayed. A 'Please enter a new filename' message prompts the user to enter a filename which has not been used previously. By examining the list displayed, it is possible to check the names that have been used before. If a name that has been used previously is typed in, then a message appears, prompting a different filename to be chosen. If the same filename needs to be used repeatedly, then it must be followed by a number, which can be incremented, such that the overall filenames are all different. The software will never accept two identical names in order to guarantee that acquired data files can never be overwritten.
- When 'Prepared' is selected, the autoruns that have been prepared, but not yet run, are listed. The message in this case prompts the user to select a name from the list displayed.
- If the 'Run' option is chosen, those autoruns that have been executed will be listed. The message prompts the user to select a name from the list displayed.

Autorun Batch Dialog Box

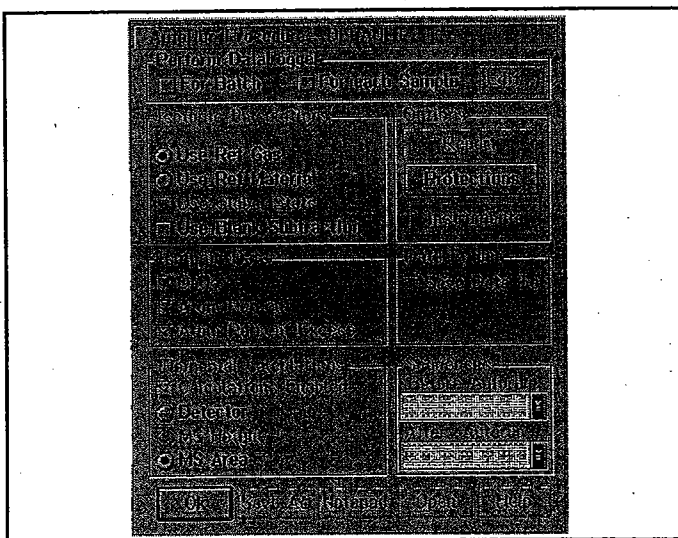

AutoRuns are setup in the 'Autorun Batch' Dialogue Box. The dialogue box can be accessed through the New, Prepared, Run, Running and Interrupted options of the 'Edit Autorun' sub-menu (cascade menu).

The dialogue box has the following features:

- 'Procedure' entry field accesses the AutoRun Procedure dialogue box. This provides the facility to set up the detailed procedures for the execution of AutoRuns.

In order to edit the procedure:

Click once on the name of the procedure entered in the 'Procedure field'.

This action reveals the 'Edit' push button. Click on the 'Edit button' once, this reveals the 'Procedure window'.

The procedure for the batch analysis of samples is set via this window. It enables the selection of a number of features required for the calculations and the final batch output.

- **Data Logger facilities** are enabled by inserting one tick in the tick boxes 'For Batch' and 'For each Sample'. It is possible to select none, either option or both options simultaneously.
When the 'For each Sample' option is selected, the 'Edit' push button appears to provide a series of windows which define the parameters which the user wishes to download to the data logger and the name of file and folder where this information needs to be stored.
When the 'For Batch' option is selected, then only the default template for this file can be used. That is, there is no optional template for batch results.
- The **'Isotopic Calculations'** can be performed either by using the reference gas or an internal standard inserted within the batch. Select the required option by pressing one of the two radio buttons.
Furthermore, if the subtraction for the potential presence of blanks is to be included, then the **'Use Blank Subtraction'** tick box needs to be ticked.
The use of **'Global Statistics'** is not available in this version of software. The facility is therefore greyed out and is not accessible.
- The **'Isotopic data'** can be reported in any of the three units specified or in any combination of these. Make appropriate selections by placing ticks in the appropriate tick boxes.
- The **'Elemental Calculations'** may be performed (if required), either by using the output signal from the TCD detector or using the output from the mass spectrometer signal. For the latter, in this version of software, the calculations are made using peak areas. In later versions of this software, it will also be possible to perform this calculation using the peak heights as acquired by the mass spectrometer. The preferred mode of calculation is selected by the choice of radio button.
- All other features shown on this window are not available in this version of software. They are greyed out and therefore not accessible.
- **'Carousel'** This file defines the characteristics of the carousel used with the elemental analyser. By clicking on the Carousel name entry field, the 'Edit' button appears. One click on the 'Edit' button reveals the carousel parameters window.

- **'Standards'** In this application, the 'standards' push button is greyed out. The use of standards is not applicable when the prep system in use is an elemental analyser.
- **'Auto Repeat'** tick boxes have the following features:
 - **'Name'**: This facility is used when entering sample details into the AutoRun Batch dialogue box. When activated, automatically enters the previously used sample Name in the sample Name entry field. If the Sample name is suffixed by a number, e.g. Sample1, the number will be automatically incremented by 1.
 - **'ID'**: This facility is used when entering sample details into the AutoRun Batch dialogue box. When activated, automatically enters the previously used sample ID in the sample ID entry field.
- **The table for Sample entries**
 - **'Type'** combo box list allows classification of the material to be analysed into Blank, Elemental and Isotopic (E & I) reference, Elemental (Elem) reference, Isotopic (Iso) reference, and Sample (Sam). Click on the combo box to make it active, then click on the right - hand, downward or upward pointing arrow to reveal the full list of options and to select one of these options.
 - **'Sam'** (sample): defines the material to be analysed as a sample material
 - **'Iso'** (isotopic reference): defines the material to be analysed as an isotopic reference, against which the isotopic compositions of samples may be calculated if so requested.
 - **'Elem'** (Elemental Reference) defines the material to be analysed as a reference material for the calculation of elemental composition of samples if this calculation is requested.
 - **'E & I'** (Elemental and Isotopic Reference) defines the material to be analysed as both an isotopic and an elemental reference, against which calculations for a sample may be performed.

IsoPrime - EA User Manual

- **'Blank'** defines the material to be analysed as a blank. A blank consists of a normal analysis cycle but in the total absence of sample material. It provides information about the signals obtained during a normal cycle, this contribution, if significant, can then be accounted for when a sample is analysed.
- **'Position'** entry field list defines the position of the sample on the carousel. It is used for information purpose only. Because the operation of the carousel is sequential only, then it is not possible to make use of the entry in this field to direct the analysis to samples other than the sample that the carousel presents to the system for analysis. The position numbers need not be entered, as they will automatically be incremented by one, each time a new line is filled.
- **'Name'** entry field list provides 32 character spaces for entering the full sample name, which is printed on the data printout. Sample names can be auto-repeated and auto-incremented.
- **'Method'** combo box list provides the facility for the selection of the appropriate method for the specified sample. Click on the entry field to activate the combo box, and use the right - hand, downward - pointing arrow to view the available methods. Click on the Edit button to access the Method Setup dialogue box.
- **'ID'** entry field list **** This facility is greyed out and is not accessible ****
- **'Weight' (mg)** entry field list specifies the weight of the material to be analysed. This needs to be entered accurately as it is used in the calculation for the elemental compositions of samples.
- **'Insert'** inserts a blank line into the autorun order for addition of samples
- **'Clear'** clears the entries along the line where the cursor is positioned.
- **'Clear All'** clears the entire autorun entries. A message will appear to prompt you to confirm that you really want to carry out this action before any clearing is actually done.
- **'Run'** initiates or re-initiates an AutoRun.
- **'Notepad'** **** This facility is greyed out and is not accessible ****
- **'Close'** closes the AutoRun Batch dialogue box. The entries are saved under the name given to this batch in the prepared autorun list.
- **'Help'** accesses the help facility associated with the AutoRun Batch dialogue box.

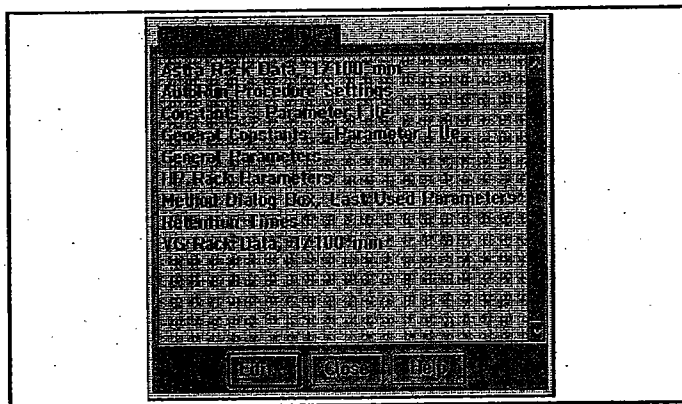

Autorun Stop

Interrupts the AutoRun in progress.

Parameter File Edit

Note: For details of the parameters see later sections of this manual.

This menu option opens the 'Parameter Files Edit' dialogue box, which allows the parameters files to be edited.

This dialogue box contains a list box containing all the parameter file names available to the user (see below), from which a file to be edited can be chosen. The dialogue box also has the following push buttons:

- 'Edit' opens the 'Edit Parameters' dialogue box, which allows you to edit any of the parameters within that file.

Each file contains one or more pages of parameters contained in entry fields, which can be changed as with any entry field. Please see the next section of this manual for details of the parameters.

- 'Cancel' exits the dialogue box.
- 'Help' gives information on the operation.

The parameter files available are:

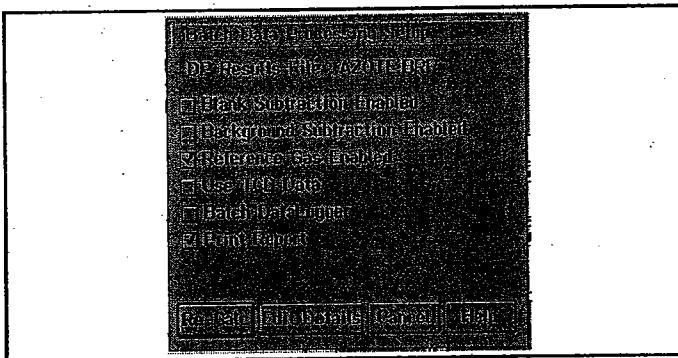

- 'Autorun Procedure Settings' accesses the threshold values for autorun protection parameters.
- 'Constants - Parameter File' accesses adjustable System and Instrument Constants.
- 'Current Rack Parameters' is not used in the EA software.
- 'General Constants' accesses fixed Instrument constants.
- 'General Parameters' accesses variable parameters associated with continuous - flow operation.
- 'HP Rack Parameters' accesses variable parameters associated with the operation of the HP7673 autoinjector.
- 'Method Dialogue Box, Last Used Parameters' accesses the set of parameters in the method that was last used.
- 'Retention Times' accesses the current values of the Retention Times universal parameters.

Batch DP Option

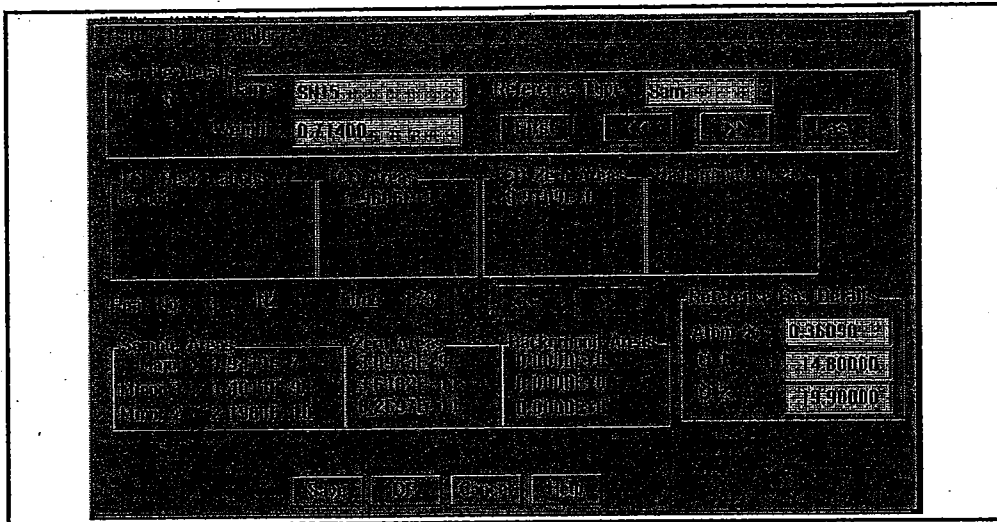

The batch DP option gives access to previously acquired data for further manual manipulation of the data prior to re-integration. Selecting this option, calls the Batch DP Report File as shown below:

The window is a full list of all the batches acquired to date and for which the data is stored on the hard disk. Any of these batches can be re-called by selecting it from this window and pressing the 'LOAD' push button. The data for this batch is loaded and the Batch Data Processing Setup window appears:

Pressing the 'Re-Calc' push button will start the re-integration process of the full batch using the instructions as defined on the Batch Data Processing Setup window. Recalculations on the full batch can be performed as many times as is required, by enabling any combination of the features offered on this window.

The 'Edit Details' push button gives access to information for each individual sample. A first window gives information on intermediate calculations; this information is non-editable and is shown in dark blue. The details, which may be altered, feature in white entry fields and include the sample name and its weight, as well as the calibration data for the reference gas used. The Batch DP Re-Analysis window is shown below:

This window contains a set of options that can be selected and deselected by using the tick boxes provided for this purpose.

From this window, it is possible to call the full manual Data Processing facilities in the software suite. These facilities are accessed by clicking on the 'DP' push button.

A full description of the manual Data Processing facilities is given in a later section of this manual.

User

The IsoPrime - EA software incorporates User levels, passwords, and a Login facility. This enables the user to protect the machine against unauthorised use, and perhaps more importantly, restrict the access of inexperienced users to portions of the software, so that the consequences of inadvertent mistakes can be avoided.

The portions of the software appropriate to the user level are:

Level 1

This allows access to sample batch entry, autorun start, and a restricted range of the manual control features.

Level 2

This intermediate level allows access to most of the manual control features of the instrument, and allows editing of selected run parameters etc.

Supervisor

Users at this level have access to all of the software.

Note: When there is no user logged in, all menus except USER and HELP are disabled.

The menu options are:

Log In

This menu option opens the 'User Login' dialogue box that allows the user to log into the system.

The dialogue box has 2 entry fields that allow the user to input their 'Username' and their 'Password'.

The dialogue box has the following push buttons:

- 'OK' checks the 'Username' and 'Password' for validity, and either exits the dialogue box if they are valid giving access to the functions of the appropriate user level or opening a dialogue box giving the reason for denied access.
- 'Cancel' exits the dialogue box without taking any actions.
- 'Help' gives information on the operation.

Log Out

This menu option when selected logs the user off the system.

Notes:

- a) Only the 'User' and 'Help' menu options are now available until the user logs in again.
- b) Even with no user logged in, the software remains running. This means that you can start an Autorun, and then logout to prevent unauthorised interruptions or access.

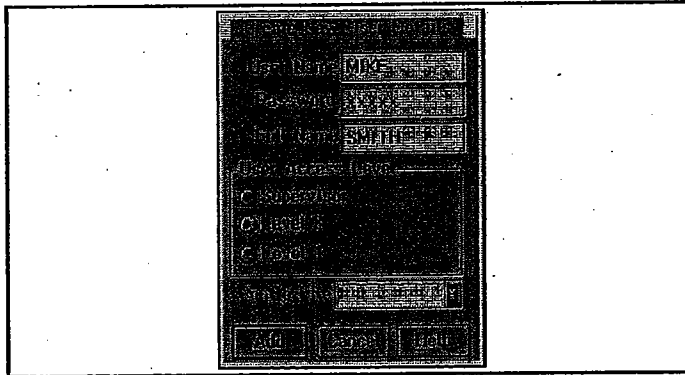

List User

This menu option opens the 'User List' dialogue box that gives a list of all authorised users.

Only Supervisor level users have access to the next group of commands in the 'User' Menu:

Create New User

This menu option opens the 'Create New User Details' dialogue box, which allows new users to be given access to the system.

This dialogue box expects the following information in the entry fields:

- **'Username'** requires the new name that the user will use to gain access to the software (up to a limit of 10 characters).
- **'Password'** requires a character set with a minimum of 5 characters known only to the new user (maximum 10 characters).
- **'Full Name'** requires the full name of the user.

The user level is then selected using the radio buttons in the 'User Access Level' section

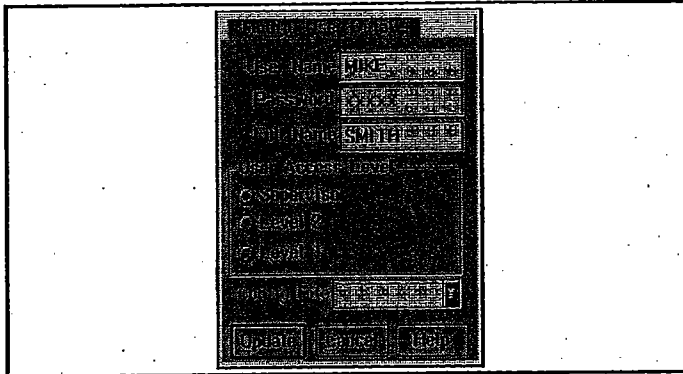

Note: The 'Config File' combo box. **** This facility is greyed out and is not accessible ****

The dialogue box then has the following push buttons:

- **'Add'** updates the user list with the new user and clears the dialogue box, allowing another user to be added.
- **'Cancel'** exits the dialogue box without taking any actions and should be used to exit the dialogue box when no further users are to be added.
- **'Help'** gives information on the operation.

Modify User

This menu option opens the 'Modify User Details' dialogue box, which allows the user access level or password to be altered.

This dialogue box expects the following information in the entry fields:

- 'Username' requires the name of the user whose details are to be modified, this once entered will load the 'Full Name' of the user, when the TAB key is used to move to the next entry field.
- 'Password' requires the new password if the password is to be modified.
- 'Full Name' gives the full name of the user once the 'Username' has been inputted.

The new user level can then be selected if required, using the radio buttons in the 'User Access Level' section

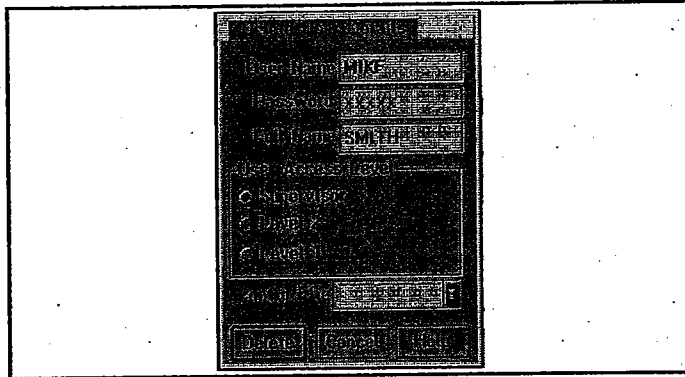

Note: The 'Config File' combo box. **** This facility is greyed out and is not accessible ****

The dialogue box then has the following push buttons:

- 'Update' changes the user access level or the password.
- 'Cancel' exits the dialogue box without taking any actions and should be used to exit the dialogue box when no further users are to be modified.
- 'Help' gives information on the operation.

Delete User

This menu option opens the 'Delete User Details' dialogue box, which allows user access to be deleted.

This dialogue box expects the following information in the entry fields:

- 'Username' requires the 'Username' whose details are to be deleted, this once entered will load the 'Full Name' of the user, when the TAB key is used to move to the next entry field.
- 'Full Name' gives the full name of the user once the 'Username' has been inputted.

The new user level is then selected using the radio buttons in the 'User Access Level' section

Note: The 'Config File' combo box. **** This facility is greyed out and is not accessible ****

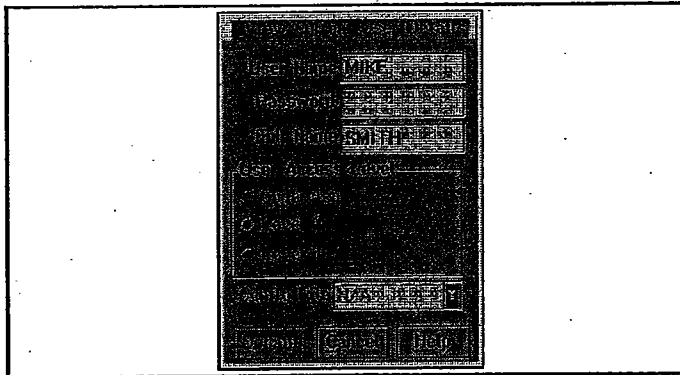

The dialogue box then has the following push buttons:

- 'Delete' opens a delete confirmation box, expecting 'Yes' (to delete the user) or 'No' (to not delete the user).
- 'Cancel' exits the dialogue box without taking any actions and should be used to exit the dialogue box when no further users are to be deleted.
- 'Help' gives information on the operation.

All users have access to the final two User menu commands.

View Own Details

This menu option opens the **'View Current User Details'** dialogue box, allows user to view their own details, except for their password.

The dialogue box then has the following push buttons:

- **'Cancel'** exits the dialogue box without taking any actions.
- **'Help'** gives information on the operation.

Change Password

This menu option opens the **'Change Password'** dialogue box, allows user to change their password.

The dialogue box has the following entry fields:

- **'User Name'** gives the present logged in user name.
- **'New Password'** requires the new password.
- **'Confirm Password'** requires the new password entered to be confirmed by re-typing the new password in this box. Failure to do this and the password will not be changed.

The dialogue box has the following push buttons:

- **'OK'** enters the new password for the user logged in.

Note: For this reason it is advisable to log out of the software when you are not present to avoid changes to your password.

- **'Cancel'** exits the dialogue box without taking any actions.
- **'Help'** gives information on the operation.

Program

One of the unique features of the IsoPrime - EA software suite is the incorporation of a powerful programming facility. This enables the user to completely program the operation of sample preparation systems, control valves, stepper motors, read all analogue outputs from the instrument (including ion beams), and to set all digital registers available via the mnemonics (e.g. retuning the ion source from a program). In short the objective is to provide all the flexibility of an interpreted language like BASIC whilst retaining all the power and facilities of the operating system and the compiled source code. For details of programming see later sections of this manual.

The IsoPrime - EA software runs using these sequence files which allows the user to modify the way their system runs if desired.

Note: Care must be taken when altering sequences to avoid damage to the system.

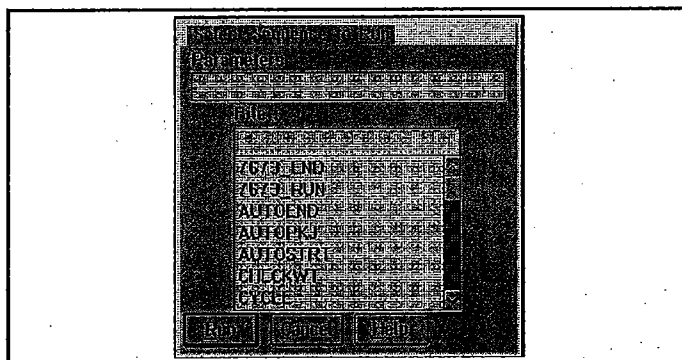

This menu gives the user the ability to use these programs individually from within the software.

The menu options are:

Run

This menu option will open the 'Select Sequence to Run' dialogue box, which executes a selected program.

This dialogue box contains a 'File' list box from which the program to be run is selected and a 'Parameters' entry field into which are put any parameters the program expects can be inputted. The dialogue box also has the following push buttons:

- 'Run' starts the selected program.
- 'Cancel' exits the dialogue box without taking any actions.
- 'Help' gives information on the operation.

IsoPrime - EA User Manual

Terminate

This menu option ends the execution of the currently running programs.

Hold

This menu option pauses the execution of the currently running programs.

Continue

This menu option resumes execution of the held program.

Config

This menu gives the user the ability to decide what is monitored in the monitor window and to tell the software the number and type of vacuum gauges that are fitted to the system, thus allowing for further expansion.

The menu options are:

Monitor

This menu option will open the 'Monitor Configuration' dialogue box. This gives a list of which vacuum gauges and detectors are used on the system and to specify where on the screen they are displayed, either in the monitor window or in the various mimic diagrams on the main screen.

The dialogue box comprises of a list box of the various vacuum gauges and detectors specified and the following push buttons:

- 'Add' when selected opens the 'Add Monitor Item' dialogue box.

This allows for further gauges and detectors to be added to the system, if the system expands. The entry fields in this dialogue box expect the following information when adding a new gauges or detector:

- 'Description' is the name of the device, and will appear in the 'Monitor Configuration' dialogue box.
- 'Mnemonic' is the mnemonic code that identifies the particular gauge or thermocouple in the software (see Table below for details).
- 'Line Number' is a number identifier that specifies where the gauge is displayed in the monitor window (up to 5 lines). If line '0' is chosen then the gauge or thermocouple is displayed only in the appropriate mimic diagram.

IsoPrime - EA User Manual

| Description | Mnemonic |
|-------------------------|----------|
| Penning Gauge | I1 |
| Analyser Backing Pirani | P1 |
| Turbo Speed | P4 |
| Magnet | MC |

This dialogue box has the following push buttons:

- **'OK'** adds the new gauge or detector to the list and updates the screen to include the new gauge, thermistor or thermocouple.
- **'Cancel'** exits the dialogue box without taking any actions.
- **'Help'** gives information on the operation.
- **'Modify'** opens the **'Monitor Configuration'** dialogue box for the gauge or detector selected from the list box in the **'Monitor Configuration'** dialogue box.

This dialogue box contains the details for the selected gauge, thermistor or thermocouple, and can be modified by changing any of the entry fields that have the same function as described above. The dialogue box has the following push buttons:

- **'OK'** will modify the gauge or detector details and update the screen.
- **'Cancel'** exits the dialogue box without taking any actions.
- **'Help'** gives information on the operation.
- **'Remove'** will remove the gauge or detector selected in the list box from the screen.
- **'OK'** will action any alterations and exit the dialogue box.
- **'Cancel'** will exit the dialogue box without taking any actions.
- **'Help'** gives information on the operation.

Gauge

This menu option will open the 'Gauge Configuration' dialogue box, This gives a list of which gauges are present on the system and their type, to enable the software to use the appropriate calibration routine, for pressure measurement.

The dialogue box comprises of a list box of the various vacuum gauges, specified and the following push buttons:

- 'Add' opens the 'Add Gauge type' dialogue box, which allows for further gauges to be added to the system in case of expansion.

The combo boxes in this dialogue box expect the following information when adding a new gauge:

- 'Mnemonic' this is the mnemonic code that identifies the particular gauge in the software (see Table above for details).
- 'Gauge Type' this is where the gauge type is specified, the options for a particular mass spectrometer are listed in this combo box, details of which are listed in the Table below.

| Gauge Type | Description |
|------------|----------------------------|
| AIM-C | Penning Gauge (type AIM-C) |
| APG-M | Pirani Gauge (type APG-M) |
| Turbo Pump | Turbomolecular Pump Speed |

IsoPrime - EA User Manual

The dialogue box has the following push buttons:

- 'OK' will add the new gauge details to the list and update the software to include the new gauge.
- 'Cancel' exits the dialogue box without taking any actions.
- 'Help' gives information on the operation.
- 'Modify' opens 'Modify Gauge Type' dialogue box for the gauge selected from the list box in the 'Gauge Configuration' dialogue box.

This box will contain the details for the selected gauge, which can then be modified by changing the 'Gauge Type' combo box (for details of the combo box see above). It will be seen that the gauge mnemonic is grey as this cannot be modified. The dialogue box has the following push buttons:

- 'OK' will then modify the gauge details and update the software to include the modified gauge.
- 'Cancel' exits the dialogue box without taking any actions.
- 'Help' gives information on the operation.
- 'Remove' will remove the gauge selected in the list box from the screen.
- 'OK' will action any alterations and exit the dialogue box.
- 'Cancel' will exit the dialogue box without taking any actions.
- 'Help' gives information on the operation.

Help

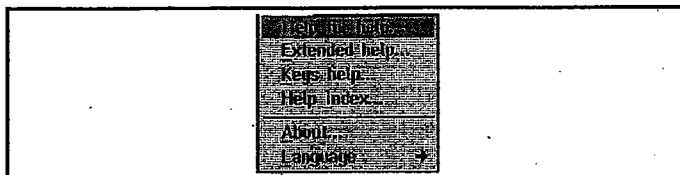

This menu allows the 'Help' facility of the IsoPrime - EA software to be accessed by the user. The 'Help' files provide a guide to the software as it is running and should be used in conjunction with this manual.

Note: As an alternative to using the 'Help' menu most windows have a 'Help' push button, which can be used to open the 'Help Window' for that section.

Help Window

Whenever a Help function is selected the information is display in the 'Help Window'. Within this window the IsoPrime - EA menu option functions are displayed as separate windows.

For further details on this window please consult the OS/2 Manual supplied with the system.

The menu options are:

Help for Help

This menu option when selected opens the '**Help for Help**' window. This details the way the help files can be accessed.

Keys help

This menu option when selected opens the '**Keys help**' window. This details the functions of the various keys e.g. Tab, Alt, etc.

Help index

This menu option opens the '**Help Index**' list box within the 'Help Window'.

From this list box the titles of the Help files are stored, therefore if for example, the file relating to Background Correction is to be found, step the list box (alphabetic order) to the section on Background Correction. Then by double clicking on the section required the Help file will then open the text available on the Background Correction so that it can be read.

About

This menu option when selected displays the '**application about box**' which details the application presently running.

Note: The 'Cancel' push button will exit this window.

Language

This menu option when selected opens a sub-menu, which enables the user to select the language for the help text.

Note: The language being used is indicated by the tick to the side of the menu items (this is not a menu on/off tick).

DP - Manual Data Processing

Introduction

The DP software allows the manipulation of data acquired in the EA acquisition software. The software package provides the facility for the modification of the parameters setup for the automatic analysis which immediately follows data acquisition. In this chapter, the tools available for manual data processing are described. The EA software utilises the multitasking capability of the OS/2 operating system to allow manual data reprocessing of archived data during the acquisition of new data.

Data Storage

After data acquisition, the data collected from the collectors of the mass spectrometer and the TCD detector are stored in a Data Processing File (.DPF) file. Also included in the .DPF file, is information from the automatic data processing integration parameters (i.e. from the Events Parameters, Acquisition Parameters, and Analysis Parameters). After automatic analysis, a second file is generated. This is a parameter file, which is suffixed by .000 during storage. This contains such information as the times of HS and RG integration windows, sample peak limits, and background ratios etc., all of which can be modified in the DP software. Once modified, the .000 file is saved as a second parameter file suffixed by .001. This stores the revised parameters. The DP package accesses both the .000 and .001 files and provides opportunity to repeat the automatic data processing.

Accessing the DP software

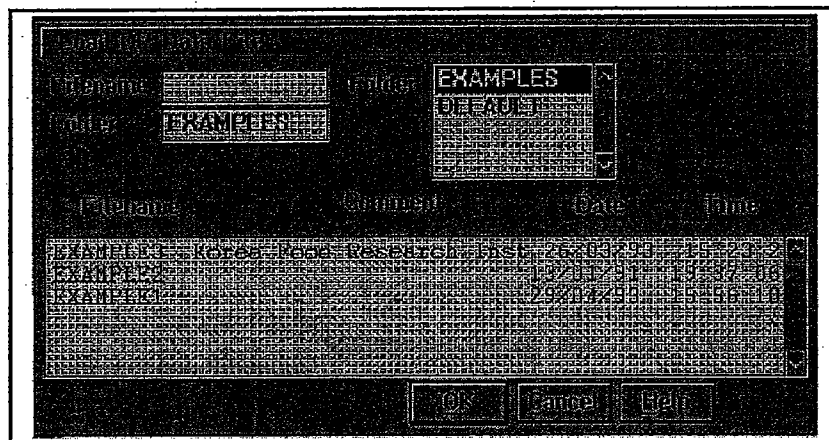

The DP software is accessed by double clicking on the DP icon in the EA folder. The DP main window will appear.

With the exception of File Menu and the Status and Help Facilities, the Menus remain inactive until either a .000 or .001 parameter file is loaded.

Loading Data

To load a DPF file into the DP software, click on the File menu and select the Load Data option. The Load DP Data File dialogue box will appear:

To load a data file:

1. Click in the desired folder name in the Folder List. The relevant folder name will appear in the Folder entry field, and the Filename List will be updated with the DPF files currently in that folder
2. Double click on the desired filename in the file list, or type the desired filename into the Filename entry field, and click on the OK button.
3. The system will automatically load that DPF file into the DP software. The DP main window will be updated with the DP graph window, in which will be drawn the TCD trace and the mass spectrometer collector traces thus:

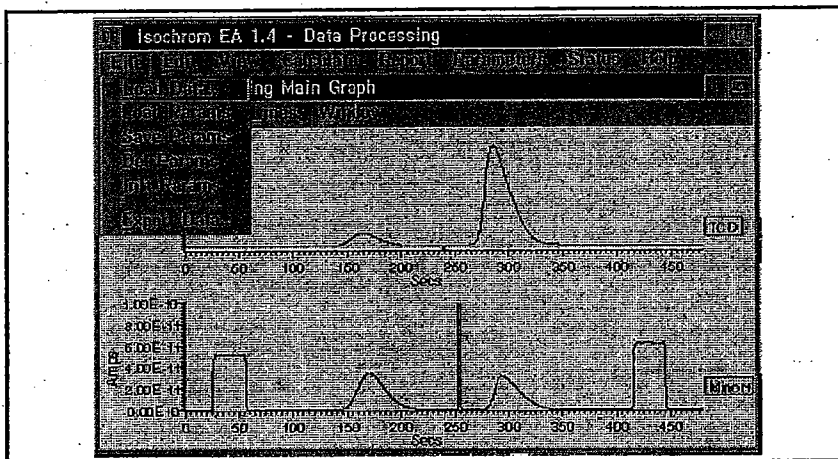

The DP main window menu bar

The menus displayed in the DP Main Window access facilities of the loading, manipulation and saving of analysis parameters, and for the printing of data.

File

The File Menu accesses facilities for the loading and storage of data and parameter files. The Menu is displayed below:

Load Data

This option accesses the Load DP Data File dialogue box described above, and allows loading of the *DPF* files into the *DP* software.

Load Params

Loads the .001 parameter file resulting from previous manual data processing activities. Once loaded, all the options on the main menu bar become active and the *DP* main graph is updated with the 2/1 and 3/1 ratio traces.

Save Params

Saves the current settings in a .001 file, overwriting any pre-existing .001 file in the process. Note when this option is chosen, the system asks for confirmation that the action be carried out.

Del Params

**** This facility is greyed out and is not accessible ****

Init Params

Loads the .000 parameter file generated after the automatic data processing.

Export Data

Access the Data Logger system for transport of data to spreadsheets.

Edit

The Edit Menu accesses facilities for the selection and deselection of sample, reference, background and zero points. It is necessary to request the 'Viewing' of these points before any manipulation from this menu can be done. This is achieved by using the 'View' menu described in the next section. The Edit menu is displayed below:

Select All

Reactivates all currently deactivated Sample Peaks, Background, Reference or Zero points displayed in the DP Graph Window

Deselect All

Deactivates all currently activated Sample Peaks, Background, Reference or Zero Points displayed in the DP Graph Window

New Point

Allows entry of new background points on the 2/1 and 3/1 ratio traces, and the collectors trace. On clicking on this command a hand icon with a pointing appears. In order to select a new point you must drag this pointer over the appropriate portion of the relevant trace.

SD

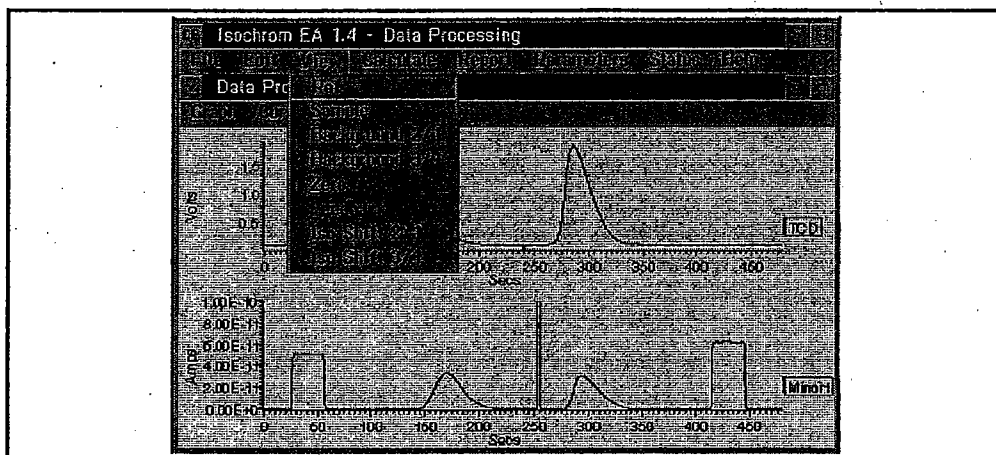

**** This facility is greyed out and is not accessible ****

Select Peak

Allows integration of unintegrated sample peaks that are smaller than the size thresholds specified in the Sample Integration Parameters.

View

The View Menu accesses options for the display of certain data points on the ratio and detector traces. The View Menu is displayed below:

Ref

Displays the 2/1 and 3/1 Reference ratio points and Reference polynomial curves on these ratio traces. It also displays the limits of integration for each reference gas pulse.

Sample

Displays the Sample Peak Limits and δ values on all integrated sample peaks on the collectors trace

Background 2/1

Displays the Background 2/1 points and polynomial curve on the 2/1 ratio trace, and the position of the background points (in grey) on the collectors trace. Active background points appear in green, whilst rejected background points are shown in red. Deactivated points turn to grey.

Background 3/1

Displays the Background 3/1 points and polynomial curve on the 3/1 ratio trace, and the position of the background points (in grey) on the collectors trace. Active background points appear in green, whilst rejected background points are shown in red. Deactivated points turn to grey.

Zero

Displays the Zero Points, and polynomial curve for each collector on the collectors trace. Active background points appear in green, whilst rejected background points are shown in red. Deactivated points turn to grey.

Iso Shift 2/1

Displays the values for the isotopic shift, for each integrated peak, between the peak maxima on the Minor1 and Major collectors

Iso Shift 3/1

Displays the values for the isotopic shift, for each integrated peak, between the peak maxima on the Minor2 and Major collectors

Calculate

The Calculate Menu accesses facilities for the recalculation of δ values after modification of any analysis parameters. The Calculate Menu is displayed below:

Re Analyse

Performs a partial re-analysis of a data acquisition using the new values of any altered parameter(s).

Full Analysis

Performs a complete re-analysis of a data acquisition, including reference pulses, using the current parameters.

Default Analysis

Performs a complete analysis of data using the initial parameters stored for the AutoDP, prior to the analysis of the sample.

Note: Analysis is only performed on one gas species at a time as the backgrounds will be different. Selection of the gas species is done from the 'Calculate' menu

Report

The report menu accesses the data printing facility for *DP*. The Report Menu is displayed below:

Results

Prints the results relevant to the last 'Re-analyse' command in the default printer.

Raw Data

Accesses a facility for transporting the raw collector readings into spread sheets. On clicking on 'Raw Data', a confirmation is required to proceed. On confirmation, a pointer symbol appears. Click-and-drag to select the interval of interest. After selection the raw data is stored in a file named 'REPORT.TXT'. An example of the contents of the text file is shown below. This text file can be read into a spread sheet, or word-processing software, or printed to the printer.

| Data File Raw Data File - EXAMPLE2 Folder - | | | |
|---|-------|---------|---------|
| EXAMPLES | | | |
| Time | Major | Minor 1 | Minor 2 |
| 1357.1 | 504 | 541 | 445 |
| 1357.2 | 500 | 537 | 443 |
| 1357.3 | 497 | 531 | 438 |

Parameters

The Parameters menu access all the integration parameters associated with the data processing algorithms. The Parameters menu is displayed below:

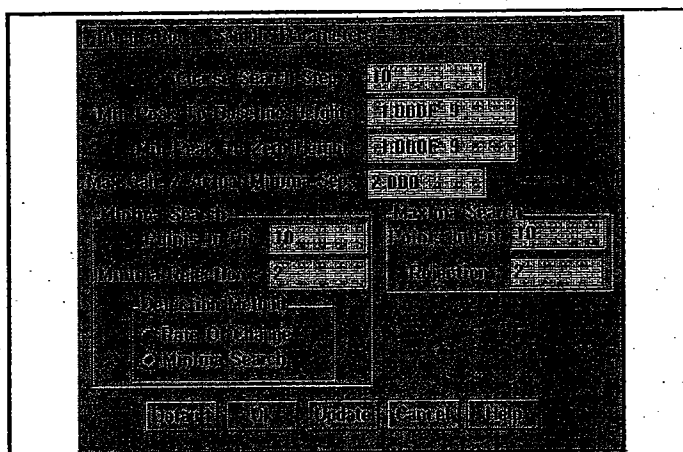

Integration Parameters

These parameters control the protocols for the data processing. The values initially displayed are stored in the .DPF file, and can be accessed after loading of the .000 parameter file by clicking on the 'Init Params' of the 'File' menu. Most of the parameters altered during data reprocessing are accessed from the integration parameters dialogue boxes. Click on the 'Integration' push button to access the **Integration - Reference Parameters'** dialogue box:

This dialogue box has the following panels:

- **'Reference Parameters'** panel has the following entry fields:
 - **'Search Interval'** is the number of data points used for searching for the reference pulses. **Note:** there are ten data points per second.
 - **'Fraction At Start'** is the fraction of the Reference pulse width at the start of the Reference Peak ignored during integration.
 - **'Fraction At End'** is the fraction of the Reference Pulse width at the end of the Reference Peak ignored during integration.
 - **'Polynomial Level'** is the order of the polynomial line drawn through the mean ratios of each reference pulse as a function of time. **Note:** it is highly recommended that this should be set to 1
 - **'Rejection Level'** is the number of standard deviations from the polynomial line outside of which individual reference points are rejected.
- **'Parameters'** panel controls the search, detection and size rejection parameters associated with the sample peak algorithms. The panel has the following push buttons:
 - **'Sample'** accesses the 'Integration - Sample Parameters' dialogue box. This dialogue box has the following features:

- 'Coarse Search Step' entry field is the number of points per step in the initial coarse search for sample peaks which should be increased to approximately 13 if peaks are missed.
- 'Min Peak To Baseline Height' entry field peaks of baseline to peak maxima height less than this value are not integrated
- 'Min Peak To Zero Height' entry field peaks of zero line to peak maxima less than this value are not integrated (see figure below)

- 'Max Calc / Actual Minima Sep.' compares the positions of the minima from the coarse search, MINIMA SEPARATION and the polynomial fit. If these are within the specified number of scans the peak limit is placed at the measured minima, otherwise the polynomial minima is used.
- 'Minima Search' panel has the following features:
 - 'Points In Fit' entry field is the number of points used in drawing a second order polynomial, around each coarse minimum, to find the exact peak limits.
 - 'Minima Rejection' entry field is the rejection level, in standard deviations, of the polynomial fit used in detecting the peak minima.

IsoPrime - EA User Manual

- 'Maxima Search' panel has the following features:
 - 'Points In Fit' entry field is the number of points used in the vicinity of the peak maximum to calculate the exact position of that maximum.
 - 'Rejection' entry field is the rejection level, in standard deviations, of the 2nd order polynomial fit used in detecting the peak maximum.
 - 'Detection Method' panel. **** This facility is greyed out and is not accessible. ****
 - 'Rate of Change' radio button **** This facility is greyed out and is not accessible. ****
 - 'Minima Search' radio button detects the preliminary peak limits by performing a coarse search for the minima on the left and right of a peak maximum.
- The 'Integration - Sample Parameters' dialogue box has the following push buttons:
- 'Default' updates the reference integration parameters to the default values. Note: default values are displayed above and are highly recommended.
 - 'Ok' saves any changes made in any of the integration parameters and closes the window
 - 'Cancel' closes the window without saving any changes
 - 'Help' accesses the help files for this dialogue box.
- 'Background' push button accesses facilities for fitting the background composition line during background subtraction. This facility is not normally used with the Elemental Analyser preparation system. It is however described in full here, in case this facility should be needed in very exceptional circumstances. Some facilities are accessed for modelling the shape of the base of each sample peak. Selecting this push button opens the 'Integration - Background Parameters' dialogue box. This dialogue box has the following panels:

- 'Background' panel has the following features:
 - 'Correction' tick box activates background subtraction procedures during Auto DP
 - 'Peak Threshold' entry field sets the trigger level for background subtraction e.g. if background height is more than 1% of total peak height then a background subtraction is performed on this particular

height then a background subtraction is performed on this particular peak. This facility enables the user to perform background subtraction for the sample peaks eluting on a significant background, whilst allowing only a zero subtraction on peaks on small backgrounds within the same chromatograph.

- **'Points Detection Method'** panel has the following features:
 - **'Left Limit'** radio button measures the background ratios on the 2/1 or 3/1 traces at the left limit time of each peak
 - **'Average'** radio button measure the background composition on the 2/1 and 3/1 traces as an average of the ratios at the left and right time limits of each sample peak.
- **'Fit'** panel has the following features:
 - **'Type - Polynomial'** radio button selects, as a polynomial, the type of curve drawn through the background composition points.
 - **'Type - Spline'** **** This facility is greyed out and is not accessible. ****
 - **'For Major - Degree'** **** This facility is greyed out and is not accessible. ****
 - **'For Major - Rejection'** **** This facility is greyed out and is not accessible. ****
 - **'For 2/1 - Degree'** sets the order of the polynomial curve drawn through the 2/1 background points (up to order 6 is allowed).
 - **'For 2/1 - Rejection'** is the rejection limit (in standard deviations) for the above polynomial.
 - **'For 3/1 - Degree'** sets the order of the polynomial curve drawn through the 3/1 background points (up to order 6 is allowed).
 - **'For 3/1 - Rejection'** is the rejection limit (in standard deviations) for the above polynomial.
- **'Baseline'** panel has the following features:
 - **'Force Horizontal'** tick box draws the doublet/multiplet baseline as a horizontal line from the lower multiplet limit, rather than joining the left and right multiplet limits.
 - **'No of Points For Check'** entry field is the number of points used to check that the peak baselines do not cut the actual beam intensity traces. If beam traces are cut, a horizontal fit is forced.
 - **'Multiplet Offset'** **** This facility is greyed out and is not accessible. ****
 - **'Max Separation For Doublet'** entry field marks as 'in a multiplet' any peak limits which are within this number of scans of the peak limits of an adjacent peak
- The **'Integration - Background Parameters'** dialogue box has the following push buttons:
 - **'Default'** updates the reference integration parameters to the default values. Note: default values are displayed above and are highly recommended.

IsoPrime - EA User Manual

- 'OK' saves any changes made in any of the integration parameters and closes the window
- 'Cancel' closes the window without saving any changes
- 'Help' accesses the help files for this dialogue box.
- 'Misc' push button accesses parameters which allow programming of the 'Zero' function and monitoring of the Isotopic Shift values. Selecting 'Misc', opens the 'Integration - Miscellaneous Parameters' dialogue box. This dialogue box has the following panels:

- 'Zero Details' panel has the following features:
 - 'Number Of Points For Zero' entry field. It is the number of data points which are to be used in order to measure the beam zeros. Data points are collected every 100 ms.
 - 'Display Zero Offset' entry field is the number of scans after the start of data acquisition after which a zero is taken. This reading used only to give approximate displayed 2/1 and 3/1 ratio traces during acquisition, and takes no part in the Auto DP
 - 'Analysis Zero Start Offset' entry field Defines the number of data points counting from the start of the acquisition after which the beam zeros will be measured.
 - 'Analysis End Offset' entry field Defines the number of data points counting from the end of the acquisition up to which the zeros will be measured.
 - 'Analysis Zero Polynomial Order' entry field describes the order of the polynomial drawn through the 'Analysis Zero Points' described in ZERO DETAILS above. It is strongly recommended that this should be set to 1.
 - 'Zero Rejection' entry field is the rejection level (in standard deviations) in the above polynomial fit.
- 'Shift Details' panel has the following features:
 - 'Polynomial Order For Shift' entry field describes the polynomial order used in the generation of the Shift Curve described above.

IsoPrime - EA User Manual

- 'Shift Rejection' entry field is the rejection level (in standard deviations) for points in the above line fit.
- 'Isotope Shift Calculation - Use Shifts' radio button disables the 'Fit to Line' feature. Individually measured peak - values each peak are used in the isotopic shift calculation
- 'Isotope Shift Calculation - Fit To Line' plots a line through the isotopic shift values for each peak as a function of time. The isotope shift value used for each peak is then read from the line rather than the individually measured peak value.

The 'Integration - Miscellaneous Parameters' dialogue box has the following push buttons:

- 'Default' updates the reference integration parameters to the default values. Note: default values are displayed above and are highly recommended.
- 'OK' saves any changes made in any of the integration parameters and closes the window
- 'Cancel' closes the window without saving any changes
- 'Help' accesses the help files for this dialogue box.

The 'Reference Parameters' dialogue box has the following push buttons:

- 'Default' updates the reference integration parameters to the default values. Note: default values are displayed above and are highly recommended as a first attempt on an unknown mixture.
- 'Save' saves any changes made in any of the integration parameters and closes the window
- 'Cancel' closes the window without saving any changes
- 'Help' accesses the help files for this dialogue box.

General

The 'General Parameters' dialogue box accesses those parameters that are external to the data acquisition. The General Parameters dialogue box is displayed below. The dialogue box has the following features:

- 'Parameters Comment' entry field will accept up to 32 characters, to enable any comment to be recorded to store along side the analysis.

IsoPrime - EA User Manual

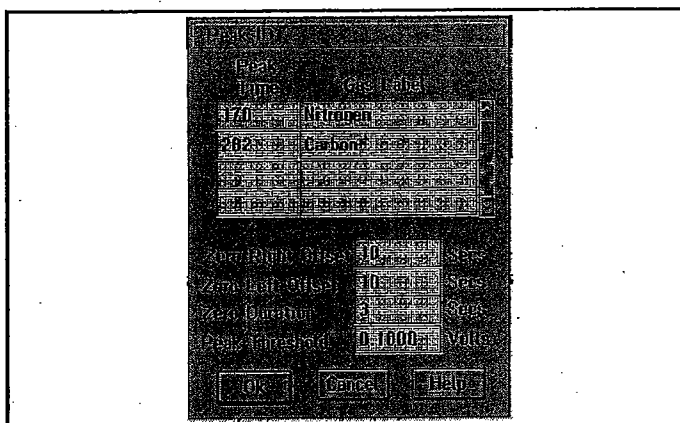

- **'Graph Threshold 2/1 and 3/1'** The entries in these two fields give the values of the major ion currents in Amps, below which the true 2/1 and 3/1 ratio traces will not be displayed. Instead a straight line will appear with an offset equal to the ratios for the reference gas pulses as acquired in the previous run..
- **'Print To File'** tick box when selected, writes the results to the text (.txt) file specified in the entry field.

The **'General Parameters'** dialogue box has the following push buttons:

- **'OK'** saves any changes made in any of the integration parameters and closes the window
- **'Cancel'** closes the window without saving any changes
- **'Help'** accesses the help files for this dialogue box.

TCD DATA

The TCD data window provides the facility to specify the parameters that are necessary for the integration of peaks acquired on the TCD, from which a calculation of the elemental composition of a sample can be made.

The peaks for which integration has to performed are specified in the upper part of this window, where the approximate time for the top of these peaks are entered. Associated with each peak a gas label may be declared. The lower half of this window provides the information needed for the integration of the TCD peaks. in the fields provided, it is necessary to declare how the zeros are to be taken and the peak thresholds below which no integration will be performed. This is to ensure that within the integration window, noisy portions are not identified as peaks.

- The **'Zero Right Offset'** indicates the time at which the right zero has to measured relative to the end of the run.
- The **'zero left offset'** indicates the time at which the left zero has to be measured relative to the start of the run.
- The **'zero duration'** indicates the length of time for which the zeros have to be measured. This time period applies to both the right and left zeros. It is not possible to declare a duration time for one of the zeros and a different duration time for the other zero.

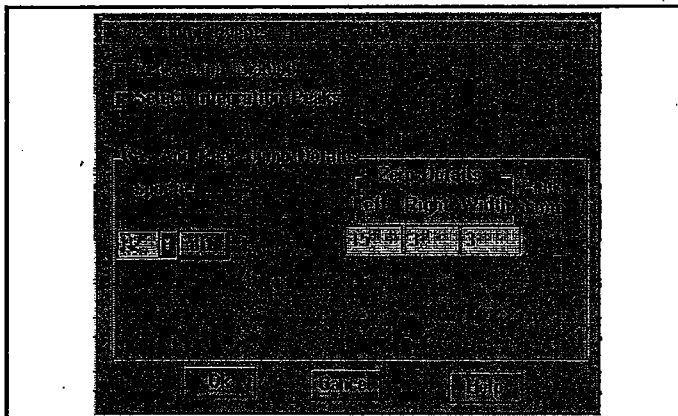

IsoPrime - EA User Manual

Notes:

All the times declared are in seconds.

If only the left zero is to be declared, then the right zero entry field must be left blank. Similarly if only the right zero is to be declared, then the left zero entry has to be left blank. If no zero subtraction is required, then both sets of entries must be left blank.

Edit Zeros/Gas

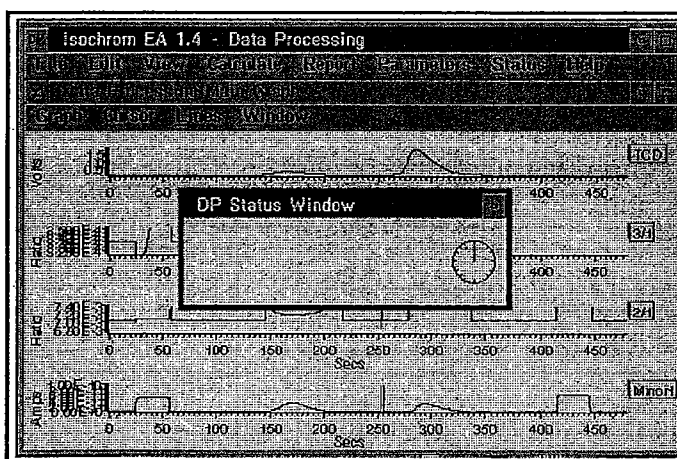

This window allows the editing of the information relating to zeros, to be changed, if it is felt necessary, in order to obtain a calculation that is more valid.

- The zero details are all measured in seconds.
- The left zero is measured from the start of the acquisition period.
- The right zero is measured from the end of the acquisition period.
- The width refers to the duration period (in seconds) during which zeros are taken. This duration period is common to both the left and the right zeros. It is not possible to declare one time period for one of the zeros and another time period for the other zero.
- The Edit push button gives access to the calibration details for the reference gas. (This window was described in a previous section)

Status

The status menu accesses the Status Window, which displays the current status of any calculations or processing activities. The Status Window is shown below:

The Status Window can be minimised to an icon. If the Status Window is not visible, click on the Status Menu. The Window should appear. If the icon is displayed, double - click on the icon to restore the Window.

Help

**** This facility is greyed out and is not accessible. ****

DP Graph Window Menu Bar

The ion beams, TCD and 2/1 and 3/1 ratio traces are displayed in the Main Graph Window. The menu bar at the top of the graph window provides facilities for manipulation of the graphic displays in the graph window. The Graph Window menu bar is shown below:

Graph

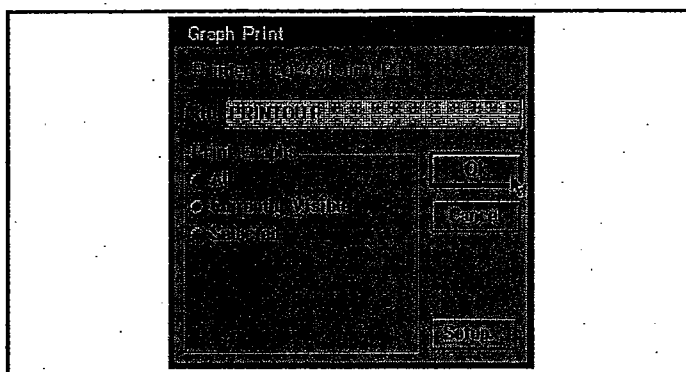

The Graph Menu provides a facility for printing of the traces displayed in the Graph Window. Before using the print options, it is necessary to set up the appropriate printer driver on the OS/2 desktop. The Graph Menu is displayed below:

This menu option has the following commands:

- 'Print'

This menu option opens the 'Graph Print' dialogue box.

This dialogue box allows the print out to be given a title in the 'Title' entry field and to select the graphs to be printed using the radio buttons in the 'Print Graphs' section. The radio buttons are:

- 'All' when selected prints all the graphs selected from scan.
- 'Currently Visible' when selected will print all the graphs in the scan window.
- 'Selected' when selected opens a list box from which graphs to be printed can be selected, by clicking on the required graph title.

The dialogue box also has the following push buttons:

- 'OK' will then start the print out.
 - 'Cancel' push button exits the dialogue box without taking any actions.
 - 'Setup' will open the 'Select Printer' dialogue box as described below.
- 'Print Setup'

This menu option opens the 'Select Printer' dialogue box. This allows the type of printer to be printed to, to be chosen. A list of available printers appears in the list box

The dialogue box has the following push buttons:

 - 'OK' will specify the printer selected in the list box as the preferred printer until changed (by selecting a different printer).
 - 'Cancel' push button exits the dialogue box without taking any actions.
 - 'Setup' will open the selected printers 'Job Properties' dialogue box, from which the print out details can be edited. For details of the 'Job Properties' dialogue box see OS/2 Manual.
 - 'Help' push button gives information on the operation.

Cursor

This menu controls the behaviour of the mouse pointer within the graphical display area. The commands all act with a 'Menu Tick' function and are:

- **'Zoom In'**

When chosen the mouse cursor becomes a magnifying glass symbol. By dragging the magnifying glass over an area of the scan it can be examined in greater detail. If required the user can 'Zoom In' in several stages.

- **'Zoom Out'**

By clicking on a 'Zoom In' graph after selecting 'Zoom Out', the plot will go back to the size previously displayed prior to a 'Zoom In', this can be done several times until the graph is back to full scale use.

- **'Full Size'**

This will return a graph to full scale, simply by clicking on the plot.

- **'Pan'**

**** This facility is greyed out and is not accessible. ****

- **'Drag'**

When Drag is selected, the mouse can be used to pick up and move any vertical cursor line used to showing on a graph. For example, it is used for moving the limits of integration and selecting the users own limits. In the DP main graph window this option also enables points to be switched OFF and reactivate them if necessary. It is used for deselecting background points on both the 2/1 and 3/1 ratio traces and also to deselect sample peaks thus eliminating these peaks from integration.

- **'Raw Data'**

Raw Data mode provides an additional vertical cursor, which can be used in conjunction with the drag facility to examine the raw data in a small window at the bottom left of the screen.

1. Select Link Zoom
2. Click on graph A
3. Click on Graph B

This menu contains a list of the lines available for display. The text in the menu is the label entered in the Scan Setup dialogue box. By ticking lines on or off from this menu the display window can be simplified.

The commands all act with a 'Menu Tick' function and are:

- **'Cascade'**

- **'Tile'**

DP - Manual Data Processing

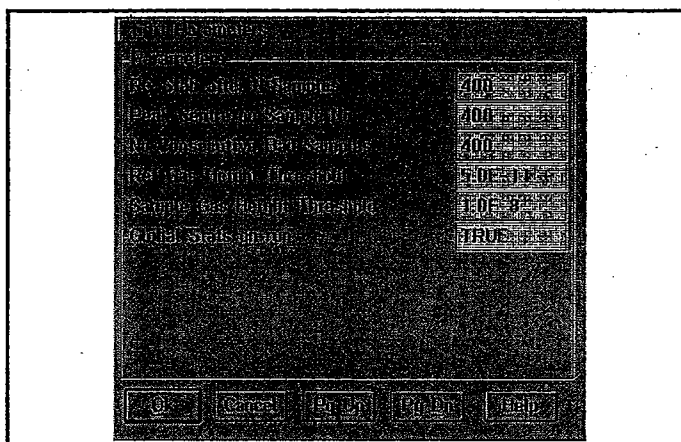

Parameter Files

The following pages of this section will give a brief description of the parameter files, for reference. For details of how to edit them see earlier in this section and for more in depth details of their function see later sections on the individual preparation systems.

The parameters for the system are set during the test and installation period and are tailored to the system, however, if desired, they can be edited to satisfy special requirements.

Autorun Procedure Settings Parameter File

The Autorun Procedures Settings parameters are shown below.

RG Stab after N Samples

Specifies the number of sample analyses (N) after which the Rctest method is activated to perform a reference gas stability run.

Peak Centre on Sample No

Specifies the number of samples (N) after which a peak centre is performed by running the Centre scan file.

No of Consecutive Bad Samples

Specifies the number of consecutive rejected samples after which an autorun will be aborted. The sample is rejected if the sample peak has a peak height less than the value entered for the Sample Gas Height Threshold parameter

Reference Gas Height Threshold

Specifies the reference gas major beam intensity below which a centre scan is triggered. The reference gas height check is performed at the end of every sample.

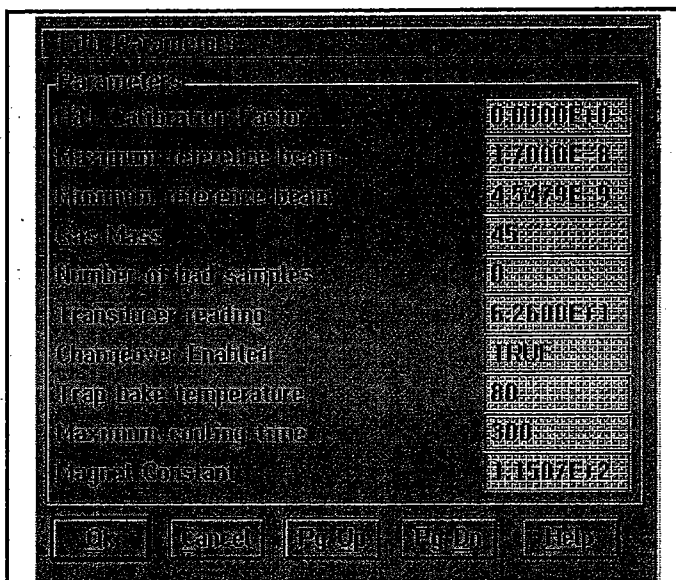

Sample Gas Height Threshold

Specifies the sample peak maximum major beam intensity below which a sample peak is rejected.. The number of consecutive rejected samples after which the autorun is aborted is specified in the No of Consecutive Bad Samples.

Global Stats on Run

**** This facility is greyed out and is not accessible. ****

Constants Parameter File

H3+ Calibration Factor

Not used on IsoPrime.

Maximum reference beam

Not used on IsoPrime.

Minimum reference beam

Not used on IsoPrime.

Gas Mass

The current axial mass is stored here (also displayed in the monitor window).

Number of bad samples

Not used on IsoPrime.

Transducer reading

Not used on IsoPrime.

Changeover Enabled

Not used on IsoPrime.

Trap bake temperature

Not used on IsoPrime.

Maximum cooling time

Not used on IsoPrime.

Magnet Constant

General Mass Spectrometer equation used when HT peak jumping and is updated when the peak is identified.

HT Settle Time

This is the time allowed after a HT peak jump for the system to settle prior to data being measured.

Hall Probe Enabled

This location stores whether the Hall Probe has been enabled.

Use Mass Cal With Hall Probe

This location stores whether the mass calibration used the Hall Probe.

Reference bellows maximum

Not used on IsoPrime.

Sample bellows maximum

Not used on IsoPrime.

Amplifier Zero Channel 0

The location of the main analyser Low 1 collector amplifier zero is stored.

Amplifier Zero Channel 1

The location of the main analyser Axial collector amplifier zero is stored.

Amplifier Zero Channel 2

The location of the main analyser High collector amplifier zero is stored.

Amplifier Zero Channel 3

The location of the main analyser Low 2 collector amplifier zero is stored.

Amplifier Zero Channel 4

Not used on IsoPrime

Amplifier Zero Channel 5

Not used on IsoPrime

Amplifier Zero Channel 6

Not used on IsoPrime

Amplifier Zero Channel 7

Not used on IsoPrime

Amplifier Zero Channel 8

Not used on IsoPrime.

Amplifier Zero Channel 9

Not used on IsoPrime.

Amplifier Zero Channel 10

Not used on IsoPrime

Amplifier Zero Channel 11

Not used at on IsoPrime

Resistor Gains Channel 0

The location of the main analyser Low 1 collector amplifier resistor value is stored. (5E+8)

Resistor Gains Channel 1

The location of the main analyser Axial collector amplifier resistor value is stored. (5E+10)

Resistor Gains Channel 2

The location of the main analyser High collector amplifier resistor value is stored. (1E+11)

Resistor Gains Channel 3

The location of the main analyser Low 2 collector amplifier resistor value is stored. (5E+8)

Resistor Gains Channel 4

Not used on IsoPrime.

Resistor Gains Channel 5

Not used on IsoPrime.

Resistor Gains Channel 6

Not used on IsoPrime

Resistor Gains Channel 7

Not used on IsoPrime.

Resistor Gains Channel 8

Not used on IsoPrime.

Resistor Gains Channel 9

Not used on IsoPrime.

Resistor Gains Channel 10

Not used on IsoPrime

Resistor Gains Channel 11

Not used on IsoPrime

Current Rack Parameters

This window includes the various parameters that are required to define the geometry and characteristics of autosamplers and autoinjectors, which may be used in conjunction with the sample preparation systems capable of being interfaced to the mass spectrometer. With the Elemental Analyser system, this window is not used.

General Parameters

RS232 Debug Enabled

When 'TRUE' is entered, any error messages associated with operation of the autoinjector are printed in the Message window

RS232 Port for Autoinjector

Specifies the computer COM port being used to communicate with the autoinjector

Show O18 Results

When 'TRUE' is entered the $\delta^{18}\text{O}$ values for each peak are printed on the results printout.

New VFC Card Fitted

Specifies the generation of VFC card currently fitted in the system controller. This is manifest as a x10 scaling factor on the FID trace.

HP Rack Parameters

This not used with the EA prep system.

Retention Times Parameter File

The retention time records the sample and reference gas retention time parameters that are global constants in the Method Setup facility.

Reference Retention Time

Specifies the delay between the RG or RN valve action, and a complete response from the mass spectrometer.

Sample Retention Time

Specifies the increased retention time resulting from a sample peak passing through the preparation interface.

IsoPrime-EA User Manual

Introduction

This section of the manual describes the step by step actions needed to get the IsoPrime and EA interface up and running from complete 'shut down'. If the instrument is in a state different to complete 'shut down', please start with the section which best represents the status of the system. This section therefore will guide the user from electrical switch on of the instrument to running a real sample.

From complete 'shut down' the entire sequence of actions is :

1. Power up the entire system.
2. Start up the software.
3. Pump the mass spectrometer
4. Set up the reference gas injector
5. Set up the mass spectrometer
6. Set up the EA and its interface
7. Perform preliminary tests to check the performance of the entire system
8. Run a standard mixture i.e. UREA
9. Run a real sample
10. Reanalyse data, if necessary

Mains voltage configuration

Rotary pump

The rotary pump may be configured for operation at 110Vac or 220Vac.

The configuration is accomplished by the operation of a rocker switch located under the top cover of the rotary pump.

The current voltage setting is displayed on a reversible plate visible through the side of the rotary pump.

The instructions given in the manufacturer's manual should be followed to change the voltage setting.

IsoPrime cubicle

IsoPrime system controller

The IsoPrime system controller contains a switched mode power supply that will operate over a range of input voltages. The mains supply should be within the range 100-300Vac for the power supply to operate.

No configuration of the power supply is required for operation at different voltages. The power supply will automatically adjust to a mains voltage within its operating range.

Turbomolecular pump controller

The turbomolecular pump controller contains a switched mode power supply that will operate over a range of input voltages. The mains supply should be within the range 100-300Vac for the power supply to operate.

No configuration of the power supply is required for operation at different voltages. The power supply will automatically adjust to a mains voltage within its operating range.

Electromagnet power supply

The electromagnet power supply will operate on 110Vac or 230Vac mains input.

The voltage may be selected using the switch mounted on the rear of the electromagnet power supply next to the mains input.

Voltage selector
switch

Electromagnet power supply voltage selector switch

Bakeout power supply

The bakeout power supply will operate on 110Vac or 230Vac mains input.

The voltage may be selected using the switch mounted on the front of the bakeout power supply next to the mains input.

Voltage selector
switch

Bakeout power supply voltage selector switch

Switching the Electrical Circuits

This section of the manual describes switching on/off the electrical circuit of the IsoPrime. The electrical circuit is separated into two halves:

1. IsoPrime.
2. Rotary pump.

Each circuit has its own mains cable, which are connected from the user's supply panel to the appropriate component.

The mains for these two circuits is supplied by the user in accordance with the site requirements guide supplied.

Switching-on the Rotary pump

This circuit supplies mains for the rotary pump.

Before following this procedure ensure that the rocker switch on the side of the rotary pump is in the off position.

Warning: Check that the voltage indicated on the side of the rotary pump is the same as the supply voltage. Should the voltage need to be changed, refer to the manufacturer's manual for details of the procedure.

Close the roughing line isolation valve mounted on the rear of the IsoPrime.

Connect the IEC cable to the socket on the side of the rotary pump and connect the other end to the mains supply.

Move the rocker switch on the side of the rotary pump to the ON position.

The rotary pump should start to operate.

Switching-on the IsoPrime

This circuit supplies the mains to the electronics units within the IsoPrime cubicle (described in the 'Electrical and Electronics' section of this manual).

Ensure that the electronics circuit mains cable (from the site service panel or transformer) is connected to the inlet on the rear of the IsoPrime cubicle.

Ensure that the mains supply to the cable is switched-on.

The fans within the cubicle should begin to operate.

Switching on the EA

The EA has its own mains supply (please refer to the Site Guide for details)

Caution: Ensure that Helium gas is flowing through the EA prior to switching the EA on

- Connect the EA mains cable to the electrical supply.
- Switch on the mains supply.
- Switch on the EA by following the manufacturer's instructions.

Switching off the Electrical Supplies

Switch off is generally in reverse order of switch on.

Note: Before switching off the electrical supplies, ensure that the system is in a safe state e.g. ion Source off, pumping system closed down, etc..

The procedure is fully described in the maintenance and fault, finding section of this manual, that is in the subsection entitled 'Venting the Mass spectrometer'.

Starting The IsoPrime-EA Software

The computer system is shipped with the instrument and has the software pre-loaded, there should therefore be no need to load the software onto the system, however the software comes with full instructions on installation (any updates of the software will also come with full instructions).

This section of the manual will therefore assume that the software is already loaded onto the computer, the computer is unpacked and the various parts of the computer system (monitor, base unit and printer) are connected together according to the manufacturers instructions (for further information refer to the manufacturers guide).

Starting Up The System Software

The following procedure should be followed:

1. Connect the computer interface cable provided between the back of the IsoPrime cubicle (below the mains input) and the Computer 'Serial 1' input.

2. Connect the mains cables of the data system to the mains supply.

Warning: Ensure that the data system is configured for the appropriate supply voltage. See the manufacturer's instructions for details of required configuration.

3. Turn on the computer, monitor and printer mains switches, this will bring up the OS/2 Desk Top.

4. Select EA icon and double click, this will open the EA folder.

5. Select the EA icon from the folder, a double click on the icon will start the software and the User Login dialogue box will appear.

Input the user name and password in the appropriate entry fields of the User Login dialogue box, and click on the 'OK' push button.

The software appropriate to the user level can now be accessed and the user has control of the instrument.

Notes:

The default 'Username' is MICROMASS and the default 'Password' is MICROMASS, which give the user supervisor level operation.

Caution: If the data system is to be accessed solely by selected users, please remove both the default "Username" and "Password" as soon as a new 'Username' and 'Password' have been set up.

- a) Refer to the fault finding section if the software fails to start.
- b) If the software has already been run and the software has been shut down with the EA folder open, then the software will re-open with this folder active and the user can start at step 5 above.
- c) If the EA icon has been placed in the 'Start-up' folder then the software will start-up at step 6 above.

Starting Up The Data Processing (DP) Software

The data can be re-analysed using the DP software, however if the system is running an 'Autorun' where the DP software is being run, then the DP software should not be selected for manual data processing. The procedure for starting the DP software is as follows:

1. Select the EA folder (see above for details of getting to the EA folder).

2. Select the DP icon from the folder, a double click on the icon will start the software and open the DP window.

3. Select 'File' from the menu bar and load the data required using the method described in the User Interface section.

The Data can now be re-analysed using the methods discussed later in this section of the manual.

Logging In

The procedure for logging

g into the IsoPrime-EA software, if the software has been just started or the software has been logged out of, is:

1. Select 'Log In' from the User menu.

Note: If the software has just been started then ignore step 1, because the software goes directly to the Login dialogue box.

2. Enter the user name and password in the Login dialogue box. The password will not be displayed on screen.
3. Click on OK.

The user is now logged into the software and has access to the functions appropriate to the user level.

Logging Out

To log out of the software, select 'Log Out' from the User menu.

The user is now logged out of the software. However, the software remains running, which means that an 'Autorun' can be started, and then logout to prevent unauthorised interruptions or access (to regain access the user will need to log in to the system again).

Configuring the system

The system can be configured for different types of gauges and where they appear on the main window. This is done normally only once at the time of installation, however if details are required, for example, if the user is adding extra preparation system, refer to the previous User Interface section of this manual under the Config menu option.

Closing Down The Software

To close the IsoPrime-EA software down, select the system menu from the main menu bar. Selecting the 'Close' Option opens the dialogue box shown below.

Choose the 'Yes' push button to shut the program down. This takes the user back to the OS/2 Desk Top screen with the EA folder open, from which the EA or the DP software can be re-started.

Note: The system controller maintains the mass spectrometer in a safe condition even though the software is inactive (the system will remain in the same state e.g. source on, valves open, etc.).

It should not normally be necessary to exit the program, as the multitasking features of the operating system remove the need to close the software down to perform other activities. However it is necessary to close down the software if the user wishes to shut down the system controller or re-read the set-up files.

Selecting the 'No' push button will ignore the close command and the software will return to normal operation.

Pumping The Mass Spectrometer

This section of the manual guides the user through the steps necessary to achieve a vacuum in the mass spectrometer. It assumes that the system is powered up. (See the section Switching the Electrical Circuits).

There is one turbomolecular pump used on the IsoPrime and one rotary pump.

To start the Analyser Rotary Pump

1. The rotary pump should be isolated from the system using the manual isolation valve mounted at the rear of the IsoPrime prior to starting the rotary pump to avoid oil vapours, which can be produced on start up, entering the high vacuum system.
2. Ensure the rotary pump power lead is connected to the rotary pump and the mains supply.
3. Switch ON the rotary pump using the rocker switch located on the side of the rotary pump.
4. Follow the start up procedure in the rotary pump manual. It is advisable to follow the gas ballast procedure to de-contaminate the pump oil and the foreline trap sieve (if the pump has not recently been used or if the oil or sieve is new).
5. When the rotary pump has been gas ballasted, set the pump to 'high vacuum' mode and gas ballast position '0' (see manufacturers guide for details), and then leave for one hour.

Starting the turbomolecular pump

When the analyser rotary pump has been running for one hour up to the isolation valve the turbomolecular pump can be started using the following procedure:

1. Select the 'Mass Spec' menu on the data system software, Select the menu option 'Turbo on'. This will turn the turbomolecular pump on. The action of powering up the turbomolecular pump will automatically close the vent valve and the pump starts to operate.
2. Immediately after step 1, open the backing line isolation valve, located on the rear of the IsoPrime cubicle. The turbomolecular pump will then accelerate to full operating speed.
3. The Pirani pressure reading (visible in the monitor window of the software) should now start to decrease. If there are no vacuum problems the pressure will continue to fall till a pressure in the 10^{-3} mbar range is achieved.
4. When the pump has reached 95% of its operating speed, the LED on the turbomolecular pump controller will light. When this occurs the AIM gauge is enabled and the source safety interlock removed. The speed of the turbomolecular pump can also be seen in the monitor window (see User Interface section).

Notes:

1. For vacuum problems refer to fault finding section of this manual or to the relevant pump manufacturers manual.
2. It may take some time for the Pirani gauge to reach its lowest value. This depends on the amount of moisture within the analyser and the backing line. When little moisture is present it may reach this value within half an hour, however if the analyser was vented on a very humid day and no precautions were taken (see the maintenance section of this manual) this may take a full day.

The vacuum gauges

The Pirani gauge is used to measure the pressure in the mass spectrometer backing line, with the pressure being displayed in the monitor window.

The AIM (Penning) gauge measures the pressure within the source housing. This value may be read from the monitor window. If there are no vacuum problems the pressure will continue to decrease steadily down to the low 10^{-8} mbar. It is not necessary to wait until this base pressure is reached before gas is admitted into the analyser. Gas may be admitted as soon as the pressure falls below $1\text{E-}6$ mbar.

Prep System Operations

NA2500 Set-up

The NA2500 should be set up in accordance with the instructions contained in it's user manual. Filling of combustion tubes, reduction tubes, water traps, the setting of flow rates for helium and oxygen, the furnace tube temperatures etc. etc. are all carried out according to the manual. In essence, the furnaces are packed as shown below:

Packing the Furnace Tubes

Setting the gas flows

The following settings can be used as a starting point but may be adjusted if a different column is substituted for that supplied by the factory or if a diluter is fitted.

Connect compressed air, oxygen and helium to the rear of the EA.

Set the pressure regulators on the cylinders as follows:

| | |
|-----------------|-------|
| He | 4 bar |
| N ₂ | 4 bar |
| CO ₂ | 4 bar |
| O ₂ | 2 bar |

Set the compressed air regulator on the front of the EA to a pressure of 50 p.s.i. (350 kpa).

Connect a bubble flow meter to Vent-R on the front of the EA and adjust the Reference helium regulator (R) until a flow of 40 ml/minute is obtained.

Connect the flow meter to Vent-M (M = measured, i.e. sample) and set a flow of 80 ml/min with the M regulator.

Set the pressure on the oxygen regulator to equal that just set on M. Connect a flow meter to Vent-O2 and set a flow of 25 ml/min with valve mounted next to the water trap in the middle compartment of the instrument. Leave the cap off the oxygen vent.

Set the knob below the oxygen regulator to FLOW. (STBY is used a night when the instrument is not in use to reduce the sample helium flow to a trickle and to turn off the oxygen and reference helium supplies.)

The knob under the compressed air regulator is the purge for the autosampler. Set it to ON.

Time and Temperature Set-up

These are the recommended time and temperature set-ups for nitrogen and carbon analysis, the oven temperature can be increased to, say 55°C, reduce the separation of the nitrogen and carbon dioxide peaks and hence the run time.

Set the following temperatures on the EA:

| | |
|---------------------------|---|
| Left (oxidation furnace) | 1030 °C (note the dial is multiplied by 10) |
| Right (reduction furnace) | 650 °C (note the dial is multiplied by 10) |
| Oven | 45 °C |
| Filament(TCD) | 190°C |

Set the following times on the EA:

| | |
|--------------|---|
| Cycle | 100 seconds (note the dial is multiplied by 10) |
| Sample start | 5 seconds** |
| Sample stop | 40 seconds |
| Oxygen stop | 60 seconds |
| Peak enable | 10 seconds (not used) |

This will be changed once the sample drop time has been established.

Setting the Sample Drop Time

Oxygen takes about 20 to 25 seconds to leave the loop and reach the oxidation furnace. Ideally, the sample should be dropped into the furnace 2 seconds before the oxygen arrives. A blank tin sample cup is used to find the time that the oxygen takes to reach the furnace, as it will only burn in its presence.

Initially, the drop time has been set to 5 seconds (Sample Start). Roll up an empty sample cup and place it in the sample drop position on the autosampler.

Press Start on the EA and be ready to press and hold "Memory" which will freeze the timer on the front of the EA. When Start is pressed oxygen leaves the loop. Look through the viewport under the autosampler. After 5 seconds the trap door will open and the sample cup will drop. When the oxygen reaches the furnace and the tin burns, the background in the viewport will change from orange to white. Press and hold Memory.

Take 2 seconds from the time displayed and enter it into the sample Start time.

Press stop.

Recheck the sample drop time until it is satisfactory.

All that remains is to ensure that the IsoPrime EA system software is able to

1. Read the TCD output signal from the NA2500.
2. Start and stop the NA2500 analytical cycle.

TCD output signal

Note. Columns must be at temperature and the TCD filament switched on.

ENSURE

0 - 10V signal out is used on the signal out connector of the EA.

GAIN BUTTON on the front panel of the EA is set to * 10.

The signal is displayed on the monitor and is labelled TCD.

Adjust the background signal by using the zero knob on the front panel of the EA such that the background is reading about 40 mV. If necessary use the coarse adjustment.

NA2500 start / stop

Note: In order to start the NA2500, the columns must be at temperature and the TCD filament switched on.

Make sure the helium purge supply to the carousel is in the ON position.

The EA start/stop operations are controlled by the mnemonics J5 and J4 on the IsoPrime EA prep system graphic. These simulate the manual equivalents in NA2500 stand-alone operation. The full sequence is as follows.

| SYSTEM OPERATION | EA EQUIVALENT |
|---|---|
| Double Click J5 OPEN i.e. START | PUSH EA START BUTTON |
| Double Click J5 CLOSE <i>EA green active light ON</i> | REMOVE FINGER FROM START BUTTON <i>NA2500 analytical cycle should commence.</i> |
| Double Click J4 OPEN i.e. STOP | PUSH EA STOP BUTTON |
| Double Click J4 CLOSE <i>Green active light switches to red i.e. OFF</i> | REMOVE FINGER FROM STOP BUTTON <i>The NA2500 will now complete a cycle as if a real sample was dropped</i> |

Setting Up the Reference Gas Injector

Power to the reference gas injector is automatically supplied when the instrument power is switched on. For operation of the reference gas injector, it is necessary to have connected the supplies of Helium and reference gasses

Single injector

The procedure for setting the single injector is as follows:

1. Set the supply Helium and reference gas pressures to 4 Bar.
2. Set the helium pressure to 1.5 psi on the pressure regulator on the reference gas injector module.
3. Set the reference gas pressure to 5 psi on the pressure regulator on the reference gas injector module.
4. At the reference gas vent, open the BMCV-1 needle valve until a strong flow of reference gas is observed. Let the reference gas purge for a period of 2 - 3 minutes to clear residual traces of atmospheric contamination.
5. Then reduce the flow of the reference gas to approximately 2 ml min⁻¹. This flow is measured by connecting a flow meter (bubble or electronic flow meter) to the vent outlet of the reference gas.
6. Check that the reference gas valve can be opened and closed by double clicking on the RG valve mnemonic on the inlet mimic diagram of the IsoPrime-EA software.

Notes:

- When the valve is open the plunger head of the valve protrudes a few millimetres from the valve head face. When the valve is closed then the plunger head is approximately level with the head face.
- If it is not possible to open or close the valve then please refer to the Fault Finding section of this manual.

Dual injector

The procedure for setting the dual injector is as follows:

1. Set the supply Helium and both reference gases pressures to 4 Bar.
2. Set the helium pressure to 5 psi on the pressure regulator on the reference gas injector module.
3. Set both the CO₂ and N₂ reference gas pressures to 10 psi on the reference gas injector module.
4. At the two reference gas vents, open the BMCV-1 needle valves until strong flows of reference gas are observed. Let the reference gases purge for a period of 2 - 3 minutes to clear residual traces of atmospheric contamination.
5. Then reduce the flows of both the reference gases to approximately 5 ml min⁻¹. These flows are measured by connecting a flow meter (bubble or electronic flow meter) to the vent outlets of the reference gases.
6. Check that the reference gas valves can be opened and closed by double clicking on the RG and RN valve mnemonics on the inlet mimic diagram of the IsoPrime-EA software in turn.

Notes:

- When a valve is open the plunger head of the valve protrudes a few millimetres from the valve head face. When a valve is closed then the plunger head is approximately level with the head face
- If it is not possible to open or close a valve then please refer to the Fault Finding section of this manual.

Setting the Mass Spectrometer

Introduction

When setting the IsoPrime mass spectrometer for the first time or after a prolonged period when the isolation valve has been kept closed, the steps involved for preparing the mass spectrometer are:

1. Admit gas into the mass spectrometer.
2. Check the analyser pressure
3. Switch the Ion source ON.
4. Coarse tune the Ion source.
5. Check the coincidence of the ion beams.
6. Check the cleanliness of the vacuum.
7. Leak check the mass spectrometer and the reference gas injector.
8. Fine tune the Ion source.
9. Check the stability of the mass spectrometer.
10. Check the linearity of the mass spectrometer

On a day to day basis, it is necessary only to fine tune the ion source and check the stability of the mass spectrometer, unless problems are encountered with the data.

Admitting gas into the mass spectrometer

Gas is admitted into the mass spectrometer by opening the Nupro isolation valve. This is a manual valve located at the inlet of mass spectrometer. It is described in section 4 of this manual.

Caution: It is strongly advised to follow the protocol described below. Failure to observe these instructions may result in damage to the instrument.

Please ensure that:

- The ion source is switched off
- The reference gas injection system is properly set up with its Helium supply turned on and that gas is flowing out of the reference open split.
- The EA sample line is connected to the splitter valve and helium is flowing.
- The reference capillary is properly connected to the tee.
- The pumping system of the mass spectrometer is fully operational and that the Penning gauge reading does not exceed 1E-6 mbar.

IsoPrime-EA User Manual

Now, follow the procedure described below:

1. Open the Nupro isolation valve
2. Initially there will be a surge of gas into the analyser, as gas trapped in the inlet capillaries is at atmospheric pressure. Monitor the pressure on the Pirani gauge and wait until it falls to $2\text{E-}2$ mbar. This should occur in 20 seconds or less.
3. Wait until the pressure shown on the Penning gauge falls below $5\text{E-}6$ mbar. If there are no major leaks along the inlet capillaries the pressure will fall quickly and settle to the operating pressure between 2 and $4\text{E-}6$ mbar. Failure to reach the operating pressure indicates major leaks. These must be cured before proceeding any further.
4. A continuous stream of Helium is now flowing smoothly into the ion source.

Switching the Ion Source ON

Caution: Ensure that the Penning gauge reading is less than $5\text{E-}6$ mbar.

To switch on the mass spectrometer source, access the Mass Spec menu in the IsoPrime-EA software. Select the **Source On** option. The source electronics will switch on.

- The instrument is now ready for tuning.

Coarse tuning the Ion Source

This section of the manual will look at tuning the IsoPrime ion source. It assumes that the mass spectrometer is to be tuned for CO_2 , however this procedure can be used for any of the other gas species. It will also assume that the source is turned ON and that gas is entering the source from the reference gas injector.

Recommended Values

Normally when an instrument is installed a set of source tuning parameters for each gas species of interest is provided for the user. However, if for any reason these are not available the following table provides a starting point, prior to optimising, for each gas species. The final optimum parameters for any individual machine may be some way from these values, there is no need to be worried if this happens.

CO_2 default source tuning parameters

| | |
|----------------------------|-------|
| Accelerating Voltage | 3.5kV |
| Extraction Voltage | 75% |
| Half Plate Differential | 0 |
| Z Plate Voltage | 0 |
| Electron Volts | 100V |
| Ion Repeller Voltage | -10V |
| Magnet Current (if fitted) | 3.5A |

Recommended Source Tuning Procedure

Note: Before the tuning procedure is started, ensure that the Reference gas valve is open.

This procedure should be followed for all gases, but in the example below, CO₂ will be the chosen gas.

This procedure assumes that the magnet is positioned correctly. If it is not then the magnet positioning procedure given in the maintenance section should be followed.

1. Load the source tuning file for the gas species to be measured, in this example CO₂. These files will have been created during the installation and have been saved under an appropriate file name. If no suitable file is available then enter the values from the table of recommended values above.
2. Adjust the accelerating voltage and/or magnet field (where an electromagnet is fitted) to focus the mass 45 in the axial collector.
3. Note: It is better to use the magnet current and only use the HT for fine adjustment.
4. Use the 'Peak Centre' command to ensure correct centering of the peak in the axial collector.
5. Run the ZV scan file and set the cursor to the maximum value.
6. Run the EX scan file and set the cursor to the maximum value.
7. Run the HP scan file and set the cursor to the maximum value.
8. Run the EV scan file and set the cursor to the maximum value.
9. Repeat the steps 6-8 until the values move by only a small amount.

Save the source tuning parameters if required.

Checking the coincidence

In order to obtain good data there must be a range of HT values for which all three beams are fully focused into their respective collectors. This is indicated, as in the trace below, by the coincidence of flat tops for each of the three ion currents over the 3545V to 3559V range

If this cannot be achieved, please, refer to the maintenance section of this manual.

The coincidence trace was obtained with the scan parameters set as shown on the window below

Cleanliness of the vacuum and Leak checking

Cleanliness of the vacuum

The cleanliness of the vacuum enclosure can be visualised by performing background scans.

Contamination may arise in a number of ways:

- Leak of atmospheric gases into the vacuum enclosure.
- Ingress of atmospheric gases into the carrier gas or the reference gas.
- Presence of a contaminant in a component of the system.
- Breakthrough of organic materials from the Elemental analyser.
- Backstreaming of oil from the pumps.

Whatever the source of contamination, it should be eliminated prior to running samples.

The traces below shows a typical background scan with a clean vacuum.

The scan parameters used to obtain the background trace showing the ingress of atmospheric gases are shown in the window below.

Leak checking

Severe leaks

If there are severe leaks within the interface or the elemental analyser this will become obvious by looking at the Penning gauge reading on the monitor window. The penning gauge may not switch on or may be reading a higher than normal pressure. In some cases the analyser backing line pressure may be high.

The Penning gauge is more sensitive to gases like Nitrogen and Oxygen than it is to Helium (a factor between 5 and 10). If significant quantities of air enter the vacuum enclosure then the Penning gauge will indicate a higher pressure.

Such large leaks are usually, only found on the elemental analyser. Close the Nupro isolation valve to the mass spec and leak check the elemental analyser according to the procedure described in its manual.

Minor leaks

Leaks may not be sufficiently significant to cause an increase in the Penning gauge reading. These leaks will cause no damage to the mass spectrometer, they must, however, be eliminated otherwise it may not be possible to achieve the desired levels of precision and accuracy for the final sample results.

This type of leak is most easily detected using Argon gas as a leak probe.

The best method to locate leaks is to perform a 'Time Scan', with the ion source tuned to Argon, that is to mass 40.

The procedure is described below:

1. Tune the ion source to mass 45.
2. With CO₂ flowing into the analyser, do a peak centre.
3. Identify mass 45
4. Select 'peak jump' by HT, specifying the mass to jump to as mass 40
5. Start a 'Time Scan', using the scan parameters shown in the window below

Blow a gentle stream of Argon at all connections starting at the high vacuum end of the system and working your way methodically all the way back to the elemental analyser, the gas plumbing and even to the gas supply bottles. When leak checking the mass spectrometer, ensure that all possible sites are investigated. The sites include the source and collector flanges, the Nupro isolation valve and all joints of the pumping system below the bench. Look for any rise in the ion current trace on the 'Time scan' trace.

- Once a leak has been located and eliminated, continue searching for leaks through the entire system, as far as the gas supply bottles

Note: Please remember that the further away from the ion source, the longer it will take the Argon gas to travel to the ion source. For example, a leak in the reference line may cause an ion current increase within a few seconds, a leak within the elemental analyser may not cause a rise in the ion current for several minutes!

Checking the system prior to running a sample

It is assumed at this stage that:

- The mass spectrometer is fully operational and a satisfactory peak shape has been achieved.
- The EA interface is fully operational with the pressures and temperatures set and stabilised.
- The instrument has been entirely leak checked.

If the instrument has not been used for some time, the checks described in this section should be made. On a day to day basis it is necessary only to perform a stability run prior to running samples.

Backgrounds

Acceptable background levels

The table below shows maximum acceptable background levels for a number of species.

| SPECIES | MAXIMUM LEVEL |
|------------------|---------------|
| N ₂ | 5E-11 |
| Ar | 5E-12 |
| CO ₂ | 5E-11 |
| H ₂ O | 5E-10 |

IsoPrime-EA User Manual

If the background levels exceed the values shown above, this is usually indicative of a leak from atmosphere (N_2 and Ar, contamination within the EA, possible excessive water content in the carrier gas (H_2O)). For further details, please refer to the maintenance section of this manual.

The backgrounds should be brought down to their acceptable levels or below, before attempting to run samples.

Fine tuning the Ion source

The multi tasking features of the IsoPrime-EA software are particularly useful for fine tuning the ion source. It is possible to simultaneously scan the peak shapes, tune the ion source, and observe the ion current intensities in the monitor window.

IsoPrime-EA User Manual

1. Start an auto-repeat scan, scanning the three collectors.
2. Choose 'Mass Spec', 'Tune Source'
3. Adjust the source tuning parameters using the recommended procedures, whilst observing the effect on sensitivity and peak shape.
4. When happy with the peak shapes and sensitivity, select 'Scan', 'Stop'.
5. Save the tuning if required.
6. Choose the scan command and perform a scan which includes both a scan of mass 45 in collector 2 and a scan of the 45/44 ratio.

Typical traces are shown below.

Note: If it is not possible to obtain at least 5 Volts of flat on the peak shape, please refer to the maintenance section of this manual.

Stability of the instrument

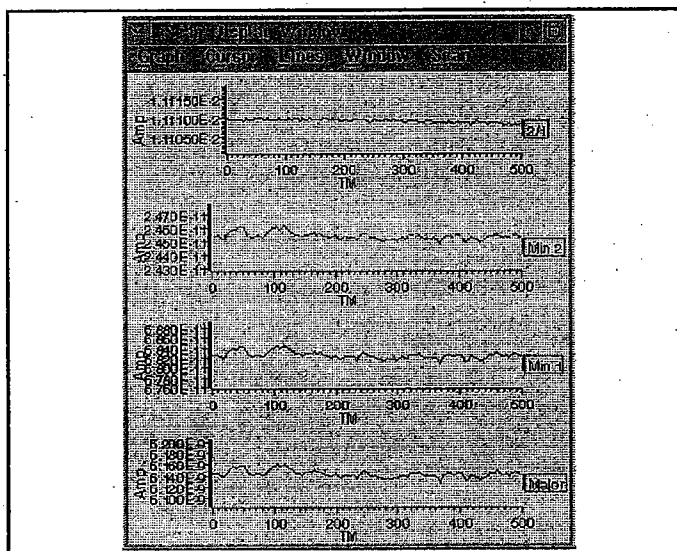

Evaluation of stability using 'Time scans'

Scans as a function of time are useful, when monitoring the stability of the system. They reveal the level of noise, the behaviour of ion currents and beam ratios as a function of time.

The parameters shown on the window below will enable the user to run a time scan for ion beams 44, 45, 46, and the ratio of beams 45/44 simultaneously, with the beams and ratio trace appearing separate graphs.

The resulting scan is shown in the figure below.

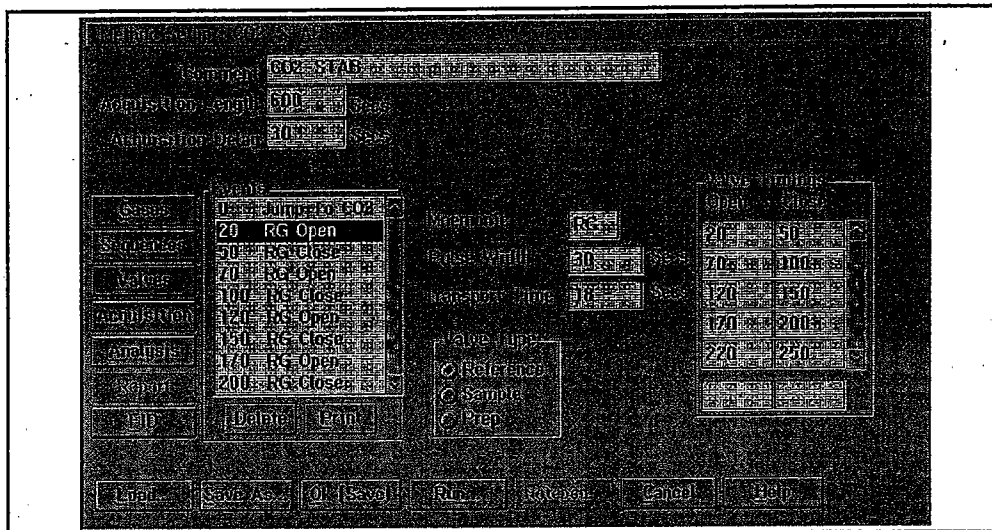

By expanding the ratio trace obtained in the 'Time scan' shown above, the average noise level for the ratio measurement can be measured. The noise in the example shown here, is contained within a band $\pm 0.00006 \times 10^{-2}$ wide. This means that the maximum precision of measurement for CO_2 that may be expected from the system is therefore around $\pm 0.005\%$.

The Reference Gas Stability Test

In order to help the user test the stability of the mass spectrometer a method has been pre-programmed and saved in a method file entitled 'CO2-Stab'. This method consists of 10 consecutive pulses of reference gas with 20 seconds between each pulse, to allow the ion beams to decay to baseline between each pulse.

The valve timings, programmed on the valve overlay of the 'CO2-Stab' method are shown in the window below.

To run the stability test:

1. Select 'Analysis'.
2. Select 'Single run'.

The Single Run window appears.

IsoPrime-EA User Manual

3. Select the method 'CO2-STAB', All other details are optional in this case.

Running an acquisition using this method yields the trace shown below.

IsoPrime-EA User Manual

The final report for this acquisition is printed below.

Folder : MS

Analysis Of Reference Gas Data

Ref Delta 13 = -36.3

Ref Delta 18 = -18.7

| Time | Major | Ratio 2/1 | Ratio 3/1 |
|----------------|----------|-----------|-----------|
| 42.3 | 1.127E-7 | 1.1104E-2 | 3.9813E-3 |
| 92.3 | 1.126E-7 | 1.1104E-2 | 3.9814E-3 |
| 142.2 | 1.127E-7 | 1.1104E-2 | 3.9814E-3 |
| 192.3 | 1.126E-7 | 1.1103E-2 | 3.9813E-3 |
| 242.3 | 1.126E-7 | 1.1104E-2 | 3.9816E-3 |
| 292.3 | 1.125E-7 | 1.1104E-2 | 3.9818E-3 |
| 342.3 | 1.128E-7 | 1.1104E-2 | 3.9818E-3 |
| 392.3 | 1.126E-7 | 1.1104E-2 | 3.9819E-3 |
| 442.3 | 1.129E-7 | 1.1104E-2 | 3.9818E-3 |
| 492.3 | 1.127E-7 | 1.1104E-2 | 3.9817E-3 |
| Std Dev Of Fit | | 1.4399E-7 | 1.2923E-7 |

Stability test report

The quantification of the stability of the mass spectrometer is indicated by the 'Standard Deviation of the Fit'

The Standard deviation of the fit in this example is 1.4399E-7

A straight line is fitted to the ten 45/44 ratios obtained from the ten consecutive pulses of reference gas by the method of linear least squares. The standard deviation of the standard errors of the points from this best fit line is calculated and reported.

A system is declared stable if the standard deviation of the fit is less than 1E-6

If this level of stability cannot be achieved, please refer to the maintenance section of this manual.

Linearity

It is essential that, whatever the ion current size within the normal measuring range of the instrument, the ion optics behave with linear characteristics.

The measuring dynamic range, defined in the specifications for this instrument, is for ion currents between $1\text{E-}9\text{ A}$ and $1\text{E-}8\text{ A}$.

Peaks eluting from the EA column have widely different heights. In order to be sure of the accuracy of measurement for a particular peak, then it must be checked that this peak has the same Delta value, whatever its height within the allowed dynamic range.

In order to help the user test the linear characteristics of the ion optics, a method has been programmed and saved in the list of methods under the name 'CO2-LIN'.

This method consists of ten consecutive pulses of reference gas spaced by 30 seconds. Whilst acquiring data using this method, it will be necessary to increase and decrease the reference gas pressure to vary the size of the ion currents for these pulses.

The procedure, for testing the characteristics of the ion optics, is described below:

1. Start an acquisition using the 'CO2-LIN' method.
2. Vary the reference gas pressure to yield pulses ranging between $1\text{E-}9\text{ A}$ and $1\text{E-}8\text{ A}$.
3. Avoid using peak heights that systematically increase or decrease. Instead use peak heights which vary randomly across the entire range. This is shown in the window below.

IsoPrime-EA User Manual

4. Examine the final output for this acquisition.

```

Analysis Of Reference Gas Data

Ref Delta 13 = -36.3

Ref Delta 18 = -18.7

| Time | Major | Ratio 2/1 | Ratio 3/1 |
|----------------|----------|-----------|-----------|
| 42.4 | 1.971E-8 | 1.1107E-2 | 3.9863E-3 |
| 102.3 | 1.978E-7 | 1.1115E-2 | 3.9856E-3 |
| 162.3 | 4.106E-8 | 1.1111E-2 | 3.9865E-3 |
| 222.3 | 1.567E-7 | 1.1114E-2 | 3.9853E-3 |
| 282.3 | 8.998E-8 | 1.1111E-2 | 3.9856E-3 |
| 342.3 | 1.310E-7 | 1.1112E-2 | 3.9851E-3 |
| 402.3 | 2.517E-8 | 1.1110E-2 | 3.9863E-3 |
| 462.3 | 1.935E-7 | 1.1116E-2 | 3.9856E-3 |
| 522.3 | 6.539E-8 | 1.1112E-2 | 3.9861E-3 |
| 582.3 | 1.037E-7 | 1.1111E-2 | 3.9853E-3 |
| Std Dev Of Fit | | 2.6175E-6 | 5.0956E-7 |

5. Plot a graph of the ratios obtained for this acquisition as a function of pulse height

6. Calculate the slope of the graph.

The system is declared to be linear provided that the slope is less than $5E-7 A^{-1}$

Sample running

Successful sample running essentially depends on

- Achievement of good chromatography on the elemental analyser with particular emphasis on peak shape and peak separation.
- Associated timing parameters as specified in the Run Method File.

Sample chromatography

Assuming the elemental analyser is set up in accordance with the instructions given in its manual, chromatography should not be a problem. If, however problems are encountered please refer to section 8 of this manual.

Run method file timings

All of the following should be related to the associated diagram showing a typical chromatographic output for both the elemental analyser and the mass spectrometer. Three sample run file configurations namely N₂, CO₂, N & C will be discussed. Topics such as Sulphur or the use of the EA diluter will be covered as an appendix. Most of the major aspects of defining the run file will be discussed for the case of nitrogen, after which subsequent run files will only contain new information specific to each. This section must be read in conjunction with section 5, the software section.

N2 Run method file

IsoPrime-EA User Manual

The following aspects of data acquisition have to be considered.

- **TCD peak elution times**

Generally nitrogen appears at 90 - 130 seconds, Carbon at 170 - 220 seconds.

TCD zero right offset. Set to 5 seconds

TCD zero left offset. Set to 5 seconds.

TCD zero duration. Set to 3 seconds.

TCD peak threshold. Set to 0.02V above TCD background.

Access from events (TCD) in method file.

- **Left and Right zero details.**

Usually, but not always, in single species method files there will be 2 points specified in the mass spec chromatogram where the background zero values are read. Normally at positions-

Z1 Left zero Set to 10 seconds from start.

Z2 Right zero Set to 10 seconds from end.

The zero width is set to 3 seconds.

The main criteria in determining the zero positions is that they should be spaced as far apart as possible and that they represent true background.

Access from events (GAS) in method file.

- **Reference Gas pulse time.**

Only one pulse is required and is introduced via the reference line prior to the arrival of the sample peak at the mass spec. For an average transport time of 12-20 seconds the reference gas valve RN is instructed to open at 20 seconds and close at 50 seconds giving a width of 30 seconds. Try to ensure that the reference pulse does not get too close to the nitrogen peak (the reference pulse should end 10 seconds or more before the nitrogen peak rises).

| RN Open | RN Closed |
|---------|-----------|
| 15 | 45 |

IsoPrime-EA User Manual

These times are entered from the events (VALVES).

The width of the reference gas pulse is user defined. It is declared on the RN valve time overlay of the Method window.

Note: The default width of the reference gas pulse is 30 seconds. This time was determined experimentally to be an optimum width. The precision of measurement may be affected if less than 30 seconds are used, it does not, however, improve for pulses longer than 30 seconds.

On 'tabbing out' of the 'RN open' field, the 'RN close' time is automatically entered by the software which takes into account the pulse width declared. The cursor then positions itself on the next line, ready to accept the next 'RN open' timing.

Transport Times for RN

This is the time that it takes for the gas to flow from the RN valve, all the way to the ion source.

To measure this time:

1. Start a Time scan and open RN at 20 seconds - let this be T_1 (seconds).
2. Wait for the pulse to elute on the ion beam trace.
3. Use the 'Raw Data' to measure the time at which the pulse starts to appear on the trace. Let this be T_2 (seconds).
4. Then the transport time is $T_2 - T_1$ (seconds).

This is the time that it takes for a reference pulse to travel from reference gas valve to the ion source.

● Defining the sample window

The sample window is defined to be that segment of the mass spec chromatogram that wholly includes the sample nitrogen peak eluting from the elemental analyser from prior to its arrival to after it has completely decayed. It is specified using the HS valve timings normally associated with the IsoPrime GC. Although this valve does not exist in the IsoPrime EA hardware, declaring its actions will define the sample window.

| | | | |
|----|--------|--------------------|-------------------------|
| HS | CLOSED | Set to 75 seconds | Start the sample window |
| HS | OPEN | Set to 140 seconds | End the sample window |

HS Valve timings

| OPEN | CLOSED |
|------|--------|
| 140 | 75 |

Times are entered from the events (VALVES)

IsoPrime-EA User Manual

Note: In the example chromatogram above there is a complication to the detection of the nitrogen peak due to the presence of CO₂ from carbon in the sample. As the CO₂ enters the mass spec 7 - 10 % of it will crack in the source to CO, which will of course be detected, like nitrogen at mass 28. The result is 2 peaks appearing on the mass spec chromatogram. HS OPEN must be set before the CO peak appears regardless of whether the Nitrogen peak has reached baseline. This complication can be removed by trapping the CO₂ out according to the directions in the elemental analyser manual. Alternatively arrange the elemental analyser conditions to give as much chromatographic separation as possible.

- Defining the sample height

To qualify as a real sample peak the peak must satisfy user defined conditions on the peak to baseline height and the peak to zero height. See section 5 for more details. Typical values are;

Peak to baseline 5E-11A

Peak to zero 6E-11A

Note: Peak to zero is usually larger than Peak to baseline providing the zero positions are specified correctly.

Conditions are set from the Analysis window overlay.

- Acquisition delay

The acquisition delay is the time it takes for the ion currents to return to their background levels after RN closes. On starting a run, RN closes automatically. The data acquisition will not start until the declared acquisition delay time has elapsed. To measure this time, please follow the procedure outlined below:

1. Open ref gas valve RN. Ion beams rise to maximum.
2. Wait 2 minutes.
3. Close RN, make a note of the time. = T₁
4. Wait till ion beams decay to a steady background value.

Make a note of the time. = T₂

The delay time is then T₂ - T₁

- Acquisition length

The length of the data acquisition depends on a number of variables.

1. The time taken for the sample peaks to elute from the elemental analyser.
2. Whether CO₂ is trapped in the elemental analyser.
3. Quality of the chromatography (tailing effects).

In general, an average time for Nitrogen would be about 240 seconds for an elemental analyser using a 2 metre column.

CO₂ Run method file

Major differences are:

1. Nitrogen does not appear on the mass spec trace, so defining the sample window is easier. Normally about 140 - 299 seconds. Specify the HS open action just before the end of the acquisition time
2. Run time is longer, normally about 300 seconds.
3. Although Nitrogen does not nominally appear on the mass spec trace, its entry to the source can affect the monitoring of CO₂ so avoid placing the CO₂ reference pulse during this time.

NC Run method file

The introduction of simultaneous acquisition of nitrogen and carbon in the same sample demands a very clear appreciation of a number of instrument and analytical characteristics.

Please refer to the example chromatogram.

The chromatogram falls easily into 3 areas.

- a) The region before the peak jump where the acquisition of Nitrogen takes place.

IsoPrime-EA User Manual

The instrument must be tuned to nitrogen. Due to time constraints associated with the peak separation it is normal to have only 1 zero position placed at the beginning of the chromatogram. The method file must include details of how the peak jump from N₂ to CO₂ and back takes place. This can be by loading tuning files, peak jumping HT or peak jumping using the magnet. The nitrogen reference valve pulse must be specified. The sample window must start before the N₂ peak appears and must end before the CO₂ reference pulse. Note the sample window encompasses both peaks.

b) The region after the peak jump where the acquisition of CO₂ takes place.

Again, due to time constraints associated with the peak separation, only 1 zero position at the end of the chromatogram will be defined. The CO₂ reference pulse must be placed after the sample window ends.

c) The peak jump itself where the transition from N₂ tuning to CO₂ tuning takes place.

The timing of the peak jump, how long to give the source to stabilise (Settle time). Defining the peak jump method (HT, tuning, magnet?) are the main considerations in this region.

Method Setup

- **Setting up peak jumping using tuning files.**

Open both reference gas valves RG and RN.

Load the nitrogen tuning file ().

Peak centre on mass 29 and save the tuning.

Load the CO₂ tuning file (CO2.TUN).

Peak centre on mass 45 and save the tuning.

Both centre voltages should be around 3.5kV Accn Volts.

Repeat this process until comfortable that switching from one tuning file to the other will result in the system being set to the centre voltage of the mass being jumped to.

Load N2.TUN again, identify mass 29, and close both reference valves.

- **Method file checklist**

Load NCRUN Method file.

Peak jump is enabled, the jump mode is set to tuning and the correct tuning files are input using the jump mode EDIT button.

Left zero position specified for N₂ in the Gas and peakjump overlay. The right field has no entry associated with it.

Right zero position specified for CO₂. The left field has no entry associated with it.

CO₂ jump time set at least 10 seconds before arrival of the CO₂ peak.

Settle time set to 6 seconds. (Allows time for the magnet to stabilise)

Sample window defined by HS starts before the nitrogen peak and ends after the CO₂ peak.

Acquisition length set appropriately.

IsoPrime-EA User Manual

- **Peak jump considerations**

Selecting peak jump using the magnet changes only the magnet current, all other source parameters remaining the same. Not normally used.

Selecting peak jump using the HT changes only the acceleration voltage, all other parameters remaining the same. Not normally used.

Both these options can be used whereby other source parameters are changed by setting up specific tuning files and enabling peak jump using source tuning.

Eg

N2X.TUN is set up as normal for nitrogen. Magnet current around 2.6 Amps, HT 3.5kV.

CO2X.TUN is set up for CO₂ at a much lower HT, around 2.6kV, but the magnet current is the same as for the N2X file. Apart from the magnet current both files are tuned independently.

If these files are incorporated into a peak jump by tuning method, then the effect will be as if peak jump using HT was enabled but with the addition of changing the other source parameters.

It is sometimes advisable to use this method of peak jumping in cases where by design or accident the peak separation is poor since any jump not involving the magnet is much faster. In this case the settle time can be reduced to 1 or 2 seconds.

Selecting peak jump using source tunings whereby both tuning files are tuned for sensitivity, both files have approximately the same HT setting at 3.5 kv and only the magnet current is very different. This is the normal method used.

- **Sample characteristic considerations**

For samples with high C:N ratios and in the absence of a diluter, special considerations have to be made in terms of how to run the sample.

In normal operation it is possible to measure up to a C:N ratio of 10:1. For ratios greater than this a method has to be found which will independently boost the nitrogen sensitivity and/or reduce the CO₂ sensitivity. One way to do this is to through source tuning manipulation. Maximise nitrogen sensitivity, save as N2X.TUN, reduce CO₂ sensitivity and save as CO2X.TUN. Use these files when setting up the method. It is possible to mix source tuning files in an autorun, but concentration measurements must then be obtained using the TCD signal from the elemental analyser.

BlankN method file

Whenever a sample is dropped into the combustion region of the elemental analyser a small but significant amount of atmospheric nitrogen is also introduced. There are two main sources of this nitrogen.

1. Air getting past the helium purging system of the carousel slides during the sample dropping action. This is the main source.
2. A small amount of nitrogen trapped inside the tin cup along with the sample.
3. An almost negligible amount associated with the tin itself.

IsoPrime-EA User Manual

The function of the N₂ blank method file is to acquire data representing the integrated beam areas produced when an empty sample cup is dropped. These integrated areas can then be used to correct the beam areas generated by a real sample.

i.e. True sample area = measured sample area - blank area

The correction is applied after all the samples and blanks have been measured.

Setting up the method file

The method file is almost identical to the N2RUN file (see above). The only additional considerations are:

Specifying peak to zero and peak to baseline to allow for the fact that the peak heights by definition will be very small.

BlankC method file

Source of the blank here is organic residues associated with the tin capsules. The Method file is almost identical to CO2RUN file apart from having to respecify the peak to zero and peak to baseline height.

BlankNC method file

Used in correcting data associated with the analysis of nitrogen and carbon in the same sample. The method file is almost identical to the NCRUN apart from having to respecify the peak to zero and peak to baseline height.

Starting a single run

Having defined a method file in terms of timings etc it must be tested prior to incorporating it into an autorun. The best way of doing this is to run any convenient sample as a single run. By use of the manual DP option (described in the next section) the resulting chromatogram can be checked for any fine adjustments in timings required by the method file.

Selecting the single run option

1. From the main menu bar, select 'Analysis'.
2. Select 'Single Run'.

3. Please ensure that the N2RUN method is selected.

IsoPrime-EA User Manual

4. Ensure, 'save data to named file' option is ticked. In this case the folder is 'Default'
5. Press 'RUN'.

The selected method file is now run.

The final report

At the end of the data acquisition, a single run, results report will be generated.

Data Processing Results

The following is an explanation of the content and terminology of the report

- Data file name Where the raw data is stored.
- Folder Where the data files are stored
- Sample name As specified
- Sample weight As specified
- Sample type Not used in single run mode
- Method The method file specified
- Batch name Not used in single run mode
- Runtime user The log on name
- Acquisition time The time the data was acquired
- Current time Always updated to present time

IsoPrime-EA User Manual

Analysis of reference gas data

- Ref delta 15 Isotopic value of the reference gas wrt AIR
- Time Centre of reference gas pulse
- Major Area in Amp.Seconds of Major beam
- Ratio 2/1 Minor1 beam area / Major beam area
- Ratio 3/1 Minor2 beam area / Major beam area
- Std Dev of fit Not valid unless there are 3 or more reference pulses. Normally there is only one.

Analysis of TCD peaks with Zero subtraction

- Time The time the peak appears at the TCD
- Label Gas species as defined in the method file at these times
- Height TCD peak height in volts
- Area TCD peak areas in volt. seconds
- T (L) Start of the peak in seconds
- T (R) End of the peak in seconds
- H (L) Background TCD signal to the left of the peak
- H (R) Background TCD signal to the right of the peak

Analysis of sample peaks with zero subtraction

- N2 time Time at which the peak appears on the mass spec
- Height Major beam height
- Area Major beam area
- 2/1 Sample minor1/major isotope ratio
- 3/1 Sample minor2/ major isotope ratio
- dN15Pk Sample delta wrt AIR
- Atom % Absolute atom% N15

Introduction to manual data processing

The data reprocessing facility (DP) exists in two forms.

- a) Manual DP which can be called from the desktop. This is generally used for re-examining data associated with single runs and is the topic of this section.
- b) Batch DP, which can be called from within the IsoPrime EA software. This is generally used for re-examining data associated with multiple sample autoruns and will be discussed later.

IsoPrime-EA User Manual

The purpose of the DP facility is to allow the user to access, manipulate and generally study in close detail all aspects of the data acquisition. Timing aspects of most of the parameters can be altered, and the data reanalysed to see what effect this has on the results. Many other aspects of the data analysis can similarly be treated. Please note however that it is not possible to gain access to or alter the fundamental raw data.

Accessing manual DP

Once a single run has been carried out in order to check the method run timings.

- The data reprocessing software is accessed through the *DP* icon in the *EA* folder. Double click on the *DP* icon to start the program. The *DP* window appears.

The menu bar of the *DP* Main Window facilitates loading of data, and loading and saving of parameter files. Once data and a parameter file are loaded, the remaining menus on the menu bar become active, and control various aspects of the display of information, and alteration of the reprocessing parameters.

Loading the single run data file

1. At the *DP* Main menu bar select the **File** menu and choose the **Load Data** option. The **Load Files** window appears.
2. A list of folders containing single run files will appear. Scroll to and double-click on the **Default** name in the folders list box. A list of single run data files within the default folder will appear. The most recently acquired will appear at the top of the list.
3. Either double-click on the file name, or click once on the file name to highlight it then click on the **OK** button. The **DP Main Graph** will then display both the TCD and Mass spec trace associated with this file.

Checking the method file parameters

1. At the *DP* Main graph menu bar select the **Cursor** menu choose the **Raw Data** option and check the actual times that the TCD and mass spec peaks appear on the chromatogram. Make a note of any changes that may be required in the method file setup.

IsoPrime-EA User Manual

At the DP data processing main menu select **File** and choose **Initialise parameters** option. The graphs will be redrawn and all of the greyed out options associated with this window will be activated. Select **View** and tick the **Zero** option. The DP main graph will be redrawn showing the position of the background zeros as specified in the method file. Make a note of any changes that may be required in the method file.

Use this feature of the software to check any other aspect of the sample run eg peak to baseline, peak to zero during the analysis of blanks etc. Once the method file parameter settings required are found close out of the DP software. Make changes in the method run file and check them out with another single run.

Closing the DP Software

To exit the *DP* software proceed as follows....

1. Use the **Save Params** option of the **File** menu to save any modified parameters in a .000 parameter file
2. Exit the DP software by:
 - either double-clicking on the **System Button** on the top left corner of the DP main window title bar (this is marked DP)
 - or click once on the **System Button** to reveal the **Window Control Menu**, then select the **Close** option
3. Click on the **Yes** button in the confirmation dialogue box.

Setting up an autorun

Introduction

The autorun facility of the IsoPrime EA software incorporates many powerful features designed to make the system as flexible and user friendly as possible. For example samples can be loaded onto the carousel and the details appended to the batch file while the autorun is running. This means the system can usefully be analysing all through the weighing procedures. A data logging facility allows for the export of data direct to spreadsheets.

Creating a new autorun file

Having characterised the order in which to run the samples, create an autorun batch file as follows.

| | | | |
|--------|---------------------|---------------------------------|------------------|
| Select | Analysis | | |
| Select | Autorun Edit | | |
| Select | New | Type the name of the batch | Select OK |
| Select | Procedure | | |
| then | Edit | to define data logging options. | |

IsoPrime-EA User Manual

Note: Performing data logger on Batch DP is the more useful data logging option at the moment. Performing data logging on each sample of a long autorun does work but the form of transfer to the spreadsheet is such that a great deal of manipulation is often required to make sense of it. The method of individual sample data logging is at present under review

DEFINE the sample details

Place cursor in **TYPE**. Select sample type using **Combo box**.

Tab to **NAME**, Insert sample title.

Tab to **METHOD**. Select method using **Combo box**.

Tab to **WEIGHT**. Insert weight in mg.

Tab to next sample

When the weight of the last sample has been entered press **RUN** to start the autorun. Do **NOT** press **RETURN** or **TAB** after entering the weight of the last sample.

Note

The first letter of the options contained in the Combo box can be used to insert the type, method, directly from the keyboard.

E.g.

In the method field type **N** to select **N2RUN**. If more than one **N** exists then repeatedly striking **N** on the keyboard will cycle through all the possibilities.

Autorun options

- **Loading up a full batch and running the autorun**

Described already in the subsection **Creating a new autorun file**

- **Updating a batch during the autorun.**

Allows for the first 6 or so samples to be loaded, the autorun to be started, and further samples to be added to the batch as the autorun proceeds. This is probably the most useful feature to the analyst as it reduces the amount of instrument idle time to a minimum. The use of this feature depends on the analytical cycle being longer than the weighing cycle. Typically 2 samples can be weighed and loaded in 5 minutes during which time only 1 sample is analysed. All that is required, as in any autorun sequence, is that the sample order running is known in advance.

Procedure

1. Weigh 6 samples. These may be blanks or reference materials or actual samples, depending on how the run is structured.
2. Load the samples on the EA carousel and set up a new autorun batch file as described in Creating a new autorun file.
3. When the weight of the last of the initial samples has been entered press **RUN**.
4. The batch file will remain at the front of the screen while the autorun begins in the background. As samples are accessed to be run, their sample details will be greyed out.
5. Weigh out more samples and load them onto the carousel. Select the next sample in the batch file by clicking on the type box with the cursor. Enter the next set of sample details.

Alternatively

After pressing **RUN** in 3 above, close out of the batch file by pressing **CLOSE**.

The system will then display the chromatogram at the front of the screen.

Weigh out the next batch of samples.

To re-enter the batch edit,

Select **Analysis**

Select **Autorun Edit**

Select **Running**

The current batch file will be loaded to which the next set of samples can be added.

Precaution

Do not allow the autorun to process the last sample in the current batch list if there are still more to add. Otherwise the current autorun will stop. If this does happen inadvertently, please see the section on **Appending to a completed run file**.

● **Appending to a completed run file**

There are situations where it makes sense to reactivate a completed autorun batch file. For example, the user may be using a batch file labelled 'testN' which is used to characterise unknown samples. The data associated with these files is not in itself important except that it allows the user to decide how best to run the sample in a 'real' run. To add samples to this file

Select **Analysis**

Select **Autorun Edit**

Select **Run**

Load the required batch file and append the sample details. Select **Run**.

IsoPrime-EA User Manual

- **Aborting the autorun**

If for any reason it is desired to halt the autorun, then

Select **Analysis**

Select **Autorun Stop**

The system will complete the present sample being analysed and then stop. If the analysis is to be stopped immediately then after selecting autorun stop,

Select **Program**

Select **Terminate**

- **Restarting an interrupted autorun**

Select **Analysis**

Select **Autorun**

Select **Interrupted**

The interrupted batch file will appear. Check that the last sample greyed out has in fact been run then press **RUN**.

Autorun batch summary report

After the final sample has been completed the batch summary report for the full autorun will be produced. A typical example of this report is shown.

IsoPrime-EA User Manual

End Of Batch Data Processing Results

The report is divided into 3 main areas.

- **Main headings**

Data file and autorun file names are the same as the autorun batch file name specified when setting up the batch.

Blank subtraction Enabled or disabled

Background subtraction Enabled or disabled. Should have no affect on the EA as background is constant

Reference gas Enabled or disabled according to whether isotopic references are included and declared as such.

Reference gas delta Reference gas values as declared in the method file.

Current time/date Always updated whenever a post data reanalysis is carried out

Elemental calculations using TCD areas Quantitative measurements using the TCD. Selected by ticking the "Use TCD Data" option in Batch data processing setup.

Average sensitivity for C or N (Vs / mg) The integrated TCD signal area produced per mg of C/N.

Elemental calculations using mass spec areas Quantitative measurements using the mass spec beam area. This is the normal default setting.

Average sensitivity for C or N (As / mg) The integrated mass spec beam area produced per mg of C/N.

- **Sample detail headings**

The number and type of headings associated with the data are obviously related to the sample analysis involved. Nitrogen analysis, carbon analysis, carbon and nitrogen analysis headings will vary slightly from each other. Nitrogen analysis will provide an atom% heading where carbon analysis does not.

- **Sample Data Output**

The number of columns displaying data depends on the analysis options chosen. All of the various options will include No, Name, Weight, Ref type information. If elemental references are included and named as such in the ref type column then quantitative details will also be shown. N and C isotope data will be shown if peakjumping is used and data on both N₂ and CO₂ has been acquired by the mass spectrometer. An elemental reference will not display the isotopic value. Instead this field will be left blank and the letter 'R' printed at the side. Blanks, labelled as blanks, will have 0.00 printed with the letter B at the side. Nitrogen data will have an atom% output. At the moment Atom% is not available on CO₂. Delta O-18 results for CO₂ can be output in the batch summary report by enabling the general parameter option 'Show O18 results'. Select analysis, parameter file edit, general parameters, edit, show O18 results -TRUE.

Spreadsheet transfer of summary report

The data summary report will be saved in the C:\isotech\EAxx\Autorun directory as a spreadsheet compatible .CSV file. If a spreadsheet is loaded onto the system then the batch .CSV file can be accessed from it. If the spreadsheet is remote from the system then copy the batch.CSV file to a floppy disc for transfer.

Batch DP post data analysis

The batch DP facility features extensive post autorun data processing. Options range from the relatively simple ability to rename samples, specify sample types, correcting errors in sample weights, to the relatively complex, such as correcting some timing errors associated with the method file, examining individual sample integration limits, and drift correction of results.

Note:

This section will be written in terms of how and as much as possible why, the operator accesses the various options associated with batch DP.

Batch DP options

The following example illustrates quantitative and isotopic measurements on samples containing small concentrations of Carbon.

Select **Batch DP**

All of the previously run batch report files will be displayed. Select the one of interest i.e. MEMSOIL1.

LOAD MEMSOIL1

The batch data processing set up window appears with the following options.

- **Blank subtraction enabled**

If blanks are incorporated into the batch and the sample type is declared as a blank then selecting this option will apply the blank correction to the result summary data.

- **Background subtraction enabled**

This option should have no effect on the data, as in a typical EA run the background is constant.

- **Reference gas enabled**

Tick this option if the delta values of the samples are to be calculated relative to the reference gas. The box should not be ticked if isotopic references are included in the autorun and their sample type is declared as such. If isotopic references are included and declared but the box is ticked then results will be calculated with respect to the reference gas.

IsoPrime-EA User Manual

- Use TCD data

Tick this option if quantitative elemental analysis is to be calculated by integration of the elemental analyser thermal conductivity detector. Otherwise the quantitative analysis will use the integrated mass spectrometer beam areas.

- Batch data_ logger

If this option is ticked then the data logger text file will be overwritten every time the summary report is re-analysed.

- Print report

Selecting this option will print the summary report.

- RE-CALC

The results summary can be recalculated, incorporating any global changes such as enabling blank subtraction or after changing some aspect of an individual sample.

- EDIT DETAILS

This option accesses the batch DP re-analysis file. The name of the sample, its type, weight, the reference gas details can all be edited and saved from this window. Also included in this window is direct access to the DP window previously described under manual DP. See section on Introduction to manual data processing.

The top section of the window includes user re-definable sample name, weight, and reference type. Below the reference type box are 4 buttons which enable the samples to be selected. Pushing 'FIRST' selects the first sample in the batch, 'LAST' the last sample. Samples in between are accessed using the right and left pointing arrowed buttons.

The centre section shows the acquired TCD sample areas with their associated background areas. The units of TCD areas are volt seconds. The TCD labels, N and C, are duplicated when peakjumping due to the way the software treats the chromatogram as a nitrogen peak with 2 TCD peaks and a carbon peak also with 2 TCD peaks.

The lower section of the window begins with a peak identification and the time it appears on the chromatogram. To access the second peak when peakjumping is involved, use the arrowed buttons to the right of the time. The sample areas are in units of ampseconds. To the right is the reference gas details box. A change made in the delta value of the first sample will apply to all of the samples.

IsoPrime-EA User Manual

When a change is made to any of these sample attributes they must be saved immediately by pressing the **SAVE** button before moving to the next sample.

If a change is made, for example, changing to a different elemental reference, pressing **cancel**, then **recalc**, will redo the batch summary report incorporating the change.

The DP button

The section Checking the method file parameters introduced the feature **Manual DP** which enables the timings and settings associated with the method file to be checked when running single samples. **Batch DP** is an extension of this feature that allows samples, incorporated into an autorun batch, to be reprocessed, by accessing the DP feature from within the **ISOCHROM EA** software. There are a number of possible reasons why problems may occur in the acquisition of data such as timings, associated with the method file most of which can be investigated using the DP button on the batch DP re-analysis page.

● Example 1

The main summary shows that data has not been acquired from the blanks, making blank subtraction impossible. Move to the sample in question. Select the DP button.

Select **File and Initialise parameters**

Select **Lines** and deselect 3/1, 2/1, minor2, minor1

i.e. Look at TCD and mass spec major only

Select **View** and choose zero

Select **lines** and deselect zero3, zero2

i.e. Only look at the major background zero

Select **Cursor** and choose the **Zoom in** option

Zoom in on both the TCD and mass spec around the time of the expected peak.

Select **Cursor** and choose **Raw data**

Note the time of the peaks, the height of the peaks, the height of the background zero.

Select **Parameters** choose **integration** select **Sample**

Check **min peak to baseline** and **min peak to zero** are set such that the small blank peak does actually meet the conditions. If not then re-edit the values.

IsoPrime-EA User Manual

Try changing the course search step to a different value, say from the default value of 10 to 15 or 20.

Select **Parameters** choose **TCD Data**. Check the timings and also that the peak threshold is set correctly.

Select **Parameters** choose **EDIT Zeros/gas**. Change the background zero positions if necessary, i.e. Edit zero details, left, right.

Whenever a change has been made, return to the chromatogram, select **calculate** and **re-analyse**. A single run report will be generated which will show if the changes made any difference. If the peak has now been acquired then double click on the **DP** button, top left on the data processing window. This action will exit the **DP** and return to **Batch DP** re-analysis, updating the data contained in the file for the blank.

Immediately select the **Save** option.

Cancel

Recalc

The system will provide an updated summary report incorporating the recovered data from the blank file.

Example 2

Samples have been run in triplicate and occasionally there is the odd set where one isotopic delta result is very different to the other two. Unlikely to be a problem with the sample itself or the elemental analyser so it would be interesting to check where the software set the integration limits for that sample.

Move to the sample in question and select **DP**.

Select **File** and **Initialise parameters**

Select **Lines** and **deselect 3/1, 2/1, minor2, minor1**
i.e. Look at TCD and mass spec major only

Select **View** and choose **Sample Printed** beside the peak will be the original calculated delta value.

Zoom in to the base of the peak. The integration limits for this sample as defined by the software will show as vertical dotted lines either side of the peak. By inspection it can be determined whether the positions defining the window are sensible or not. In 99.9% of cases they will be. However if it is found necessary to redefine this window.

Select **Cursor** and choose the **drag** option.

The cursor will change to a cross hair. Position over the left or right vertical limit, hold the left mouse button down and drag the limit to a new position.

Select **Calculate** and choose **Re-analysis**. The system will recalculate the delta using the new integration window.

Exit and save as in example 1

Example 3

When comparing standard reference materials placed at the beginning and end of an autorun and the delta values have shifted slightly, it is possible to disable the reference gas calculations and use instead the standard materials to recalculate the run.

Go to the Batch DP Re-analysis page and move to the reference material sample at the beginning of the run. Change its **Reference type** from **Sam** to **Iso**. Select the edit option and define the delta value associated with the reference material. **Close** and **save**.

Move to the reference sample at the end of the run and repeat as above.

Cancel out of the DP Re-analysis window to the **Batch Data Processing setup** window. Disable the **Reference gas enabled** by removing the tick in its selection box.

Select Re_calc

The data will be re-analysed using reference standards combusted in the elemental analyser.

IsoPrime-EA User Manual

Introduction

The purpose of this chapter is to describe the remaining features of the software package. As such it is essentially an Advanced User's guide, which describes briefly aspects of the package which enable users to 'customise' the appearance and operation of their software.

Descriptions are also included of the interface to 'add-in' features such as the 'ISOLINK' remote modem support package.

System Files

Various files are used by the software to set-up the behaviour and layout of the system. These include files to define the appearance of pull-down menus, mimic diagrams, and parameter files. Further files are used to define the programs used to run samples in an Autorun, and perhaps most interestingly for the advanced user, files can be written which allow full programming control of instrument and sample preparation system operation.

Editing and Creating Files

The simplest way to edit system files is with the OS/2 System Editor. If this is not on the OS/2 Desktop, it can be found by opening the 'Productivity' Folder in the 'OS/2 System' folder. Alternatively, open an OS/2 Window from the Command Prompts, and type 'E' at the C: prompt.

Note: The facilities available in the OS/2 System Editor are fully described in the OS/2 manuals, which should be referred to in this section.

When saving a file, the user will be prompted to define a file type. All files should be identified as 'Plain Text', which are simple ASCII Text Files. Use the Save-As command to save the file in the appropriate directory and always use the correct filename extension:

| | | |
|-------|---|------------------------------|
| *.SEQ | - | sequence files |
| *.PRM | - | parameter files |
| *.TXT | - | menu and Mimic diagram files |

It is also possible to create system files using a more sophisticated package, such as Microsoft Word. However it is essential to save such files as **Text only**, as the software will not expect to encounter any hidden formatting characters.

Parameter Files

The values of any of the system parameters can be changed from the Analysis menu, using the Parameter File Edit commands. The actual files however contain much more information. Parameter Files are found in the directory C:\ISOTECH\EA\PARAMS. Their filenames have the form *.PRM.

Format

An example of the format is shown below:

```
1 'Manifold Parameters'
'20 Sample - B Bank Fitted' = FALSE BooleanT 1
'Use Crackers' = FALSE BooleanT 1
'Pumpout Time' = 60 IntegerT 1
'Sample Transfer Time' = 30 IntegerT 1
'Sample Release Time' = 15 IntegerT 1
```

The first line is the text which will appear in the Parameter Files list box on selection of the Parameter File Edit command in the user interface. It is preceded by a number which indicates the minimum User Level needed to access the file from software (see user levels in the User Interface Section of this manual).

Note: The text must be included in quotation marks ('').

Each subsequent line details one parameter, and has the general form:

'Text' = Value, Type, User Level

Text

This must be included in quotation marks, and is the text which will appear in the Parameter File Edit dialogue box. This may be written in a foreign language if required. This text is also used by the IMPORT and EXPORT commands (see later).

Value

This is the value initially assigned to the parameter. It must be in the appropriate format and range for the type of variable used.

Type

This declares the parameter type. Valid selections are:

| | | |
|-----------|---|------------------------|
| BooleanT | - | logical, TRUE or FALSE |
| IntegerT | - | integer numbers |
| RealT | - | real numbers |
| CardinalT | - | Cardinal numbers |
| StringT | - | string of characters |

User Level

A number from 1 to 3 declaring which levels of user have access to changing the parameters.

Text Files

The appearance of Mimic Diagrams on your screen is controlled by a set of files found in the

C:\ISOTECH\EA\SETUP\ directory

All these files have names of the form *.TXT.

CFMIMIC.Txt

This file contains a list of the mimic diagram file to be used on the system.

Mimic Diagrams (*.TXT)

These contain details of the icons for valves, bellows, pipework, thermocouples, pressure gauges, etc., which appear on screen.

The Isochrom EA example below demonstrates the principles involved.

| Isochrom Elemental Analyser | |
|------------------------------------|----------------------|
| Object GC 200 72 | ELEMENTAL ANALYSER |
| Object MassSpec 52 47 | MASS SPEC |
| Mnemonic J5 Valve 190 125 Vert | START VALVE |
| Mnemonic J4 Valve 220 125 Vert | STOP VALVE |
| Mnemonic XD Interface 235 135 Horz | STOP WORD |
| Mnemonic XE Furnace 205 135 Horz | START WORD |
| Mnemonic RG Valve 125 37 Horz | RG (CO2 VALVE) |
| Mnemonic RN Valve 125 13 Horz | RN (N2 VALVE) |
| Mnemonic VY Valve 125 105 Horz | VY (DILUTER VALVE) |
| Mnemonic HS Valve 150 160 Vert | SAMPLE WINDOW |
| Mnemonic IM Valve 100 160 Vert | PENNING GAUGE ENABLE |
| pipe 00 100 82 190 85 | EA HORIZONTAL |
| pipe 00 100 40 160 43 | RG HORIZONTAL |
| pipe 00 100 15 160 18 | RN HORIZONTAL |
| pipe 00 100 70 103 110 | SAMPLE VERTICAL |
| pipe 00 100 15 103 55 | REF VERTICAL |
| pipe 00 70 67 103 70 | MS SAMPLE PIPE |
| pipe 00 70 55 103 58 | MS REF PIPE |
| pipe 00 100 107 160 110 | VY HORIZONTAL |

The first line is text, which appears on the Title Bar of the mimic diagram window. This is followed by a line which describes each icon to be drawn in the window, with each icon corresponding to a mnemonic (which must be a valid mnemonic for your system). Three types are available, illustrated below in example lines.

Mnemonic RG Valve 125 37 Vert

Tells the system to draw a valve icon at co-ordinates x=125, y=37 with respect to the 0, 0 corner of the mimic diagram window. This will correspond to Mnemonic RG, and will be labelled as such on the window.

Note: Valves can be shown in either vertical 'Vert', or horizontal 'Horz' orientation, to better illustrate the connectivity of the system.

PIPE n x1 y1 x2 y2

Icons drawn in the mimic diagram window can be shown connected by lines of varying thickness. The command in the *.TXT file takes the form:

The number n is not currently used. The co-ordinate pairs x1 y1 and x2 y2 define a rectangular area of pixels with respect to the 0, 0 position of the window. This will be filled in grey to form a pipe or connection on the finished screen display.

User Menus

It is possible to add customised commands and procedures (written as *.SEQ files) to certain of the pull down menus.

The files C:\ISOTECH\EA\SETUP\USERMENU.TXT contains a list of editable commands on the Inlet, Mass Spec, and Prep menus. An example is shown below. The file contains one line for each added menu command.

Each line has the following format:

Text : number : *.SEQ : optional parameters :

Text is the text which will appear on the pull down menu. If a character is preceded by a tilde (~), then that character will appear underlined, and can be used for keyboard operation via the 'alt' key. Note that the text may be written in a foreign language if required.

Number is a key to the menu on which the command will appear. Valid selections are

- 2 - Inlet menu
- 7 - Mass Spec menu

***.SEQ** is the name of a valid sequence file in the C:\ISOTECH\EA\SEQUENCE directory. This sequence will be executed when the menu command is selected.

Optional Parameters are added if the named *.SEQ file expects to receive parameters, they should be placed here, separated by either spaces, or commas.

Note: If no parameters are passed, the line has the form.

Text ; number ; *.SEQ;;

Using CSV Format Files

The **Datalogger** facility in the software suite stores raw results information in files where each data item is separated by a comma. This gives rise to the term CSV (Comma Separated Variables). Such files can be imported into third party suites for further processing.

The details of how to read in such files will vary from one spreadsheet package to another. The example below describes how to import a file into Microsoft Excel 5.0 running under Windows.

From the **File** menu, choose the **open** command.

Set the directory to **C:\ISOTECH\EA\DATA**

From the '**List Files of Type**' box, choose the **Text Files** options.

Click on the file name, then **OK**.

The file will now be imported into Excel.

Note: Because the software is multitasking, the spread sheet programs can be used while the IsoPrime is carrying out analytical work, maximising the productivity.

Compressing and Archiving Data

If the Datalogger system is being used to store the raw data, it is good practice to copy the files onto media which can be stored in a safe place.

Files may be copied from the C:\ISOTECH\EA\DATA directory onto the a:\ drive using either the Drives program from the OS/2 system folder, or perhaps more easily using the copy command from an OS/2 Window e.g.:

COPY C:\ISOTECH\EA\DATA*.TXT A:

would copy all *.TXT files into the current directory on the disk in drive A.

If the data is required compressed it is recommended that a more sophisticated compression package such as 'PKZIP' or 'LHA' is used.

Programming The IsoPrime-EA

One of the unique features of the IsoPrime-EA suite is the incorporation of a powerful programming facility. This enables the user to completely program the operation of sample preparation systems, control valves, stepper motors, read all analogue outputs from the instrument (including ion beams), and to set all digital registers available via the mnemonics (e.g. retuning the ion source from a program). The language includes all arithmetic operations, real, integer and logical variable types, conditional statements, IF's GOTO commands, labels, subroutine calls etc.

In short the objective is to provide all the flexibility of an interpreted language like BASIC whilst retaining all the power and facilities of the operating system and the compiled source code.

Program Language Syntax

Commands

Commands available are :

OPEN mnemonic

Opens the valve identified by mnemonic

CLOSE mnemonic

Closes the valve identified by mnemonic

START mnemonic

Turns on the switch identified by mnemonic

STOP mnemonic

Turns off the switch identified by mnemonic

ANOUT mnemonic,value

Sets the specified analog output to the desired value

STEPOUT mnemonic,value

Tells the stepper motor identified by mnemonic to move to position identified by value

Read Statements

Read Statements available are :

READBEAM mnemonic, variable

- Reads the specified ion beam, the mnemonics are:
 - J0 Major
 - J1 Minor 1
 - J2 Minor 2
 - J3 Minor 3

READMOTOR mnemonic, variable

- Reads the position of the stepper motor identified by mnemonic and stores the result in variable.

READVALVE mnemonic, variable

- Reads the state of the valve and stores the result in the variable (Boolean)

DIGIN mnemonic, variable

- Reads the digital signal identified by mnemonic and stores the result in variable

ANIN mnemonic, variable

- Reads the analog signal identified by mnemonic and stores the result in variable (which must be real).

- For example:

- ANIN T1,FINGERTEMP

- Reads thermocouple 1 (the cold finger) and stores the result in FINGERTEMP

Declarations

Declarations available are:

INTEGER list of variables

- Declares a list of variables as of integer type: an integer can be in the range -2,147,483,648 to +2,147,483,647

REAL list of variables

- Declares a list of variables as of real type. A real can be in the range +/- 2.3E-308 to +/-1.7E308 with 15 digits of precision.

BOOLEAN list of variables

- Declares a list of variables as of Boolean type (i.e. Logical) type. A BOOLEAN variable may adopt the value TRUE or FALSE

FLAG list of variables

- Declares the variables as GLOBAL booleans. This means that they will be valid in all programs which are running concurrently.

STRING list of variables

- Declares a list of variables as of string (i.e. text/character) type. STRING variables may be up to 80 characters long.

String Handling Commands

APPEND StringVariable StringVariable/String

- Appends the second parameter to the first string.

PREPEND StringVariable StringVariable/String

- Prepends the second parameter to the first string.

COMPARE BooleanResultVariable StringVariable StringVariable/String

- Compares the first string to the second and if they are the same then returns true.

SLICE StringVariable StartPosition Length StringVariable/String

- Copies the portion of the last string from the 'start position' for the next 'length' characters into the first string.

VALSTR String ASCIIValue

- Converts the ASCII value into a character and returns it as a string.
- **Note:** ASCII codes can be used in String commands APPEND, PREPEND and ASSIGN by preceding the number with the @ symbol (e.g. ASSIGN Cr @10 would put the ASCII text for the character 10 into the string Cr).

STRVAL ASCIIValue StringVariable/String

- Returns the ASCII value of the first character in the string.

Assignment Statements

Assignment Statements available are:

ASSIGN variable,value

- Sets variable to value

ADD variable, value1, value2

- Adds value2 to value1 and stores the result in variable

SUBTRACT variable,value1, value2

- Subtracts value2 from value1 and stores the result in variable

MULTIPLY variable,value1, value2

- Multiplies value1 by value2 and stores the result in variable

DIVIDE variable, value1, value2

- Divides value1 by value2 and stores the result in variable

OR Variable Boolean1 Boolean2

- Performs a logical OR on the 2 booleans and stores the result in the variable

NOT Variable Boolean1 Boolean2

- Performs a logical NOT on the booleans and stores the result in the variable

AND Variable Boolean1 Boolean2

- Performs a logical AND on the booleans and stores the result in the variable

Program Flow Control

Program Flow Controls available are:

IF value1, conditional, value2, label

- Compares value2 to value1; if the conditional operator ($=$, $>$, $<$) is satisfied, the statement is TRUE, and execution will proceed at the line following "label". Otherwise execution will proceed at the next line.

:label-name

- A valid label name is an alphanumeric string preceded by a colon. Label-names are referred to by GOTO and IF statements.

GOTO label

- Execution proceeds from the line after the label referred to.

EXIT ReturnVal

- Ends the program, returning the real variable ReturnVal to the calling program. The last line of the program must be an EXIT.

CALL return variable SEQUENCE FILENAME <parameters>

- Starts execution of the program specified by SEQUENCE FILENAME. Any required parameters must be passed. The execution of the calling program is suspended until the called program executes an EXIT statement. The Return value of the EXIT statement is stored by the calling program in return variable.

SPAWN SEQUENCE FILENAME <parameters>

- Starts execution of the program specified by SEQUENCE FILENAME. Any required parameters must be passed. The execution of the Spawning program continues, so that the two programs run in parallel. No return variables are possible.

WAIT value

- Waits for value seconds before proceeding with the program. Value may take the form of a suitable variable name.

Input/Output

Input/Output available are:

MESSAGE colour number String

- Sends a text message to the message window. The message is shown in the specified colour. String contains the text to be output. The contents of a variable can be output by specifying the variable name preceded by a \$ (e.g. MESSAGE -1 Value is \$Val would output the contents of a variable Val).

- Note: Upto five variables can be used in one message.

- The main colour numbers are:

| | | | | | |
|----|------------|---|-----------|----|------------|
| -2 | White | 4 | Green | 10 | Dark red |
| -1 | Black | 5 | Cyan | 11 | Dark Pink |
| 0 | Background | 6 | Yellow | 12 | Dark Green |
| 1 | Blue | 7 | Neutral | 13 | Dark Cyan |
| 2 | Red | 8 | Dark Grey | 14 | Brown |
| 3 | Pink | 9 | Dark blue | 15 | Pale Grey |

- By convention, red should be reserved for error or warning messages.

QUESTION Answer_Variable String

- Opens a question dialogue box on the screen. String contains a prompt to the user which requires a yes/no response. If the response is Yes, the Boolean answer_variable is set to TRUE, if no it is set to FALSE. This enables the user to control the flow of execution of the program.

Communication with Communication (Com) Ports

SETUP Comport BaudRate Parity DataBits Stopbits
SoftwareHandshaking HardwareHandshaking

- Opens the communication port with the specified settings

PUTPORT ErrorVariable PortMessage

- Writes one character to the communication port:

READPORT ErrorVariable Port Message

- Reads a string from the communication port. This will read until the terminator string is returned.

GETPORT ErrorVariable Port Message

- Writes one character to the communication port then read one character immediately.

WRITEPORT ErrorVariable Port Message

- Writes a string from the communication port.

READPORTFILEIN ErrorVariable Port FileName

- Reads text from the communication port and writes it out to the file C:\ISOTECH\DI\FileName.PRT. It will keep reading until the terminator is received.

WRITEPORTFILEOUT ErrorVariable Port FileName

- Reads the text file C:\ISOTECH\DI\SETUP\FileName.PRT and writes it to the communication port.

Errors

- The values returned as errors from the communication port are as follows:
 - 0 - OK
 - 1 - Unknown Error
 - 2 - Cannot read from or write to the port

Communication Routine Parameters

Maxresp

- Is an INTEGER with a default of 50 characters to read (Note: 0 will give as many characters as needed).

Timeout

- Is an INTEGER with a default of 10000 milli-seconds to wait for a response.

WaitTime

- Is an INTEGER with a default of 100 milli-seconds to wait before re-trying the communication port.

Retry

- Is an INTEGER with a default of 1 times to re-try writing to the communication port.

RdTerm

- Is an STRING with a default value of CrLf. The communication port will be read until the read terminator is received.

WrTerm

- Is an STRING with a default value of CrLf. The communication port will be written to until the write terminator is sent.

If any other settings are required declare the variable of the correct type and assign the required value.

Note: This must be done in each sequence using the communication port commands. If any variables are undeclared the default value is used.

Miscellaneous

Miscellaneous commands available are:

JUMP value HTJump PeakCentre

- Jumps to the mass specified by value, using HT if HTJump is set TRUE or by Magnet if HTJump set FALSE. If PeakCentre is set TRUE it will perform a peak centre after the jump.

LOAD Tfname 255

- Retunes the ion source by loading the specified tuning file. The 255 is a bit set value which specifies which of the source parameters to load (e.g. 1 = HT only, 4 = Half Plates only, etc.).

Mnemonics

- Mnemonic 2 letter identifiers for valves switches etc.

string

- Any set of alpha-numeric characters.

Variable Names

- Variable Names consist of a string, started by a letter, of between 3 and 12 characters. The names are case sensitive.
- FINGtemp and FingTEMP are different variables.
- Before use, a variable name must be declared in a REAL, INTEGER, or BOOLEAN declaration statement.

Parameters

- A parameter is identified by a % symbols
- e.g. WAIT %0
- Will use the value passed in to the sequence as the first parameter.

Comments

- A line is treated as a comment if its first character is %

IMPORT variable name, '*.PRM', 'Text'

- Will read the value of the parameter identified by 'Text' from the parameter file *.PRM, and store the result in variable name. This command thus enables sequences to import values from parameter files.
- **Note:** If, and only if, a variable is imported from a parameter file, it does not need to be declared in an BOOLEAN, REAL, INTEGER etc. statement. This is because the parameter file will define the variable type.

IsoPrime-EA User Manual

EXPORT variable name, '*.PRM', 'Text'

- Will write the value of variable name to the file *.PRM, stored on the new value of the parameter identified by 'Text'.
- **Note:** variable must be of the same type as that defined in the parameter file.

PARK mnemonic

- Where mnemonic is a valid stepper motor, this command steps the motor device back to its zero reset position, as controlled by the appropriate expanded position.

CONTROL TEMP Mnemonic Setpoint Duration.

- This will allow the device identified by Mnemonic to be controlled at Setpoint (°C) temperature for the specified duration (minutes).

CONTROL TEMP STATUS Mnemonic Status Variable name

- This will query the status of the temperature device identified by Mnemonic. Status values returned are
 - -998 - no control in progress
 - -999 - device tripped
 - Other value - temperature reading (°C)
- and will be stored in the Integer variable given as status variable name.

ABORT CONTROL TEMP mnemonic

- This will abort a temperature control operation.

IDENTIFY MASS

- This will update the current mass, setting the relevant beam mappings. Mass should be the mass of the species to identify.

BEEP frequency duration

- This will sound the computer speaker

Parameters are:

frequency – an integer value representing the frequency (Hz) of the tone to be sounded.

Duration – an integer value representing the time (ms) that the tone is to be sounded for.

An Example Program

```
% An example program
% This program illustrates some of the features available
% It monitors the pumpout of the reference gas by measuring the major beam
intensity. If it does not fall sufficiently in a given time, the user is asked if they
want to try again
% Declare variables
INTEGER Pumptime,Counter
REAL Majorbeam,Allgone
BOOLEAN Answer

% Initialise variables
ASSIGN Pumptime, 60
ASSIGN Allgone 1.0E-12
ASSIGN Counter,0

% Set valves to pump out reference
OPEN LV
OPEN RP
OPEN RF
OPEN RV
OPEN RM

% Set changeover valve to reference
CALL Dummy SETCHOV.SEQ TRUE

:Pumpout
ASSIGN Counter,0

:Loop
WAIT 5

% Read Majorbeam
ANIN J0, Majorbeam

% Increment the loop counter
ADD Counter,Counter,5
IF Counter < Pumptime Loop

% has the gas been pumped out?
IF Majorbeam < Allgone Finish

% The gas has not all been evacuated
QUESTION Answer Pumpdown too slow -Do you want to continue?
IF Answer = FALSE Quit

% The user wants to retry the pumpout
GOTO Pumpout

:Quit
MESSAGE -1 Program Aborted
GOTO END

:OK
MESSAGE -1 Reference evacuated OK

:END

% Close all valves
SPAWN CLOSEDIV.SEQ
EXIT 0
```

Good Practice When Programming

Make the first line of a program a comment which identifies the author, date of revision and purpose of the program

Declare all variables at the start of the program

Use self-explanatory variable names

Use frequent comments.

Break programs down into subroutines using labels and comments, and use CALL, rather than writing complex programs that are hard to follow and may be too lengthy.

Use integer variables and arithmetic where the precision of real variables is not absolutely needed.

Take back ups of your program on floppy disc.

Running a Program

Choose the PROGRAM, RUN option from the main menu bars

Select the program to run from the dialogue box which appears: remember to enter any necessary parameters using the parameter entry field.

Press OK or Return to start the program.

Editing a Program

A program can be entered on the IsoPrime data system by using the OS/2 System editor, which is a powerful text processor. It has extensive search and replace features and on screen editing facilities, such as cut and paste, which are similar to those provided by any Text processing software. Fonts and text colours are also selectable. A detailed manual for this editor is provided with the system.

Note: Because the software is multitasking, programs can be written while the IsoPrime is carrying out analytical work, maximising the productivity. However be careful not to modify sequences which are currently running.

Testing a Program

The best way to test a program is to run it first using the off-line software which is provided with the system. Again, the productivity is maximised, and the programs can be tested without risking damage to the instrument, however sequence commands setting the bellows, motor positions, etc. will obviously not drive the specified devices while running off-line.

IsoPrime-EA User Manual

Introduction

This section of the manual will give details of the routine maintenance and fault finding of the IsoPrime-EA. It is important that routine maintenance is carried out on a regular basis, as this will improve the reliability of the instrument and in turn the quality of the results when running real samples. There are two things to bear in mind before attempting any maintenance or fault finding:

- Read the manufacturers guides supplied for the details of routine maintenance for the components of the system e.g. Rotary pumps, Turbomolecular pumps, Air Compressors, Elemental analyser, etc.
- Fault finding and system repairs should be carried out by a suitably qualified technician. Please contact the Customer Service Department at Micromass or the local Micromass representative with any queries.

Toolkit

The IsoPrime is supplied with a toolkit containing the following components.

Pliers, snipe nose.

Eye magnifier.

Adjustable wrench, 6".

Spanner, open ended, 3/4".

Spanner, open ended, 1/2-9/16".

Spanner, open ended, 3/8-7/16".

Spanner, open ended, 1/4-5/16".

Jewellers screwdriver 0.4mm.

Screwdriver, dumpy, flat 5mm.

Screwdriver, flat 3mm.

Hex key 10mm.

Balldriver 3mm.

Balldriver 5mm.

Additional components supplied within the installation kit are:

Ceramic capillary cutter.

Source assembly jig.

Useful Tools

Additional tools that may be of use in performing the routine maintenance tasks described in this section of the manual.

Set of metric Allen keys (hexagon keys)

Pair of tweezers

Lint-free gloves (dental gloves are ideal i.e. non-powdered)

A digital multimeter

Medium size screwdriver (straight head)

Medium size screwdriver (Philips head)

Set of Jeweller's screwdrivers

Emergency fault conditions

Emergency Instrument Shutdown

Warning: Before returning the power to the system ensure the reason for the shutdown is corrected.

In exceptional circumstances (such as fire or exposure to hazardous voltages) it may be necessary to shut down the instrument quickly. If such a situation arises, the instrument should be isolated from the electrical supply, as close to the supply as possible:

- Isolate the supply at the distribution box that connects the instrument and the preparation system to the site supply, if this can be done quickly. This will usually mean operating the isolation lever on the outside of the box.
- Switch off the rotary pump by the toggle switch on its side, and then unplug the mains inlet cables from the rotary pump and the rear of the IsoPrime cubicle.
- Switch off the mains power to the elemental analyser and then unplug its mains inlet cables (see manufacturer's guide for details).
- Disconnect the power cables of any peripherals connected (such as sample preparation systems, etc.).
- When there is no further risk to personnel:
 - Close the rotary pump isolation valve.
 - Turn off the power switches to the PC, Monitor and Printer.
 - Set to zero all the temperature settings on the elemental analyser. (See manufacturers guide)

Electrical power failure

Warning: Repair the Electrical fault before returning the power to the system.

If the power supply to the instrument fails for any reason (e.g. during an electrical storm) the following procedure should be followed:

- Close the rotary pump isolation valve.
- Switch off the rotary pump by the toggle switch on its side.
- Switch off the power to the IsoPrime cubicle, or remove the IEC connector.
- Switch off the mains power to the elemental analyser (see manufacturer's guide for details).
- Turn off the power switches to the PC, Monitor and Printer.
- Set the elemental analyser temperatures to zero. (See manufacturers guide)

When the failure has been rectified:

- Follow the standard power-up procedure for the Pumps/Electronics.
- Follow the standard power-up procedure for the elemental analyser.

Other supplies failure

Compressed Air

Warning: To avoid possible eye injury, wear eye protection when using compressed gas.

If the compressed air fails the valves on the reference gas injector and the GC interface will close and fail to open.

The reason for the compressed air failure should be located and rectified. This could include:

- Check the air compressor (see manufacturers guide).
- Check air lines.
- Check for blockages.

Supply gases

Helium

Caution: Failure of the Helium flow may damage the mass spectrometer, and thermal conductivity detector. The performance of the separation column and combustion tubes may also be significantly affected.

It is essential that the Helium flow not be interrupted whenever the elemental analyser is switched on, or the Nupro isolation valve is open.

If Helium is not flowing constantly, air will enter at the open splits and flow into the mass spectrometer. The source filament may be damaged.

It is strongly advised to carefully monitor the amount of gas remaining in the helium supply bottle, in particular before leaving at night and at weekends!

Oxygen

The continuous availability of oxygen is essential to the operation of the elemental analyser. No damage to the mass spectrometer or elemental analyser will result if the oxygen supply fails but there will be an obvious degradation in analytical performance.

Reference Gas

No damage to the instrument will result if the carbon dioxide or nitrogen supply runs out. However, if this occurs during an acquisition it will not be possible to obtain a Delta calculation with respect to the reference gas.

Carbon dioxide is usually in the liquid phase, when stored in pressurised reservoirs. This makes it difficult to monitor the amount of gas remaining in the bottle. Additionally, as the bottle becomes empty, the gas has a tendency to fractionate, that is, its isotopic composition changes. If this occurs, loss of accuracy will result.

As a rule of thumb, it is wise to change the CO₂ reference gas bottle as soon as the bottle pressure starts to fall. This indicates that only CO₂ in gas phase remains, suggesting that most of the gas has already been used.

Nitrogen bottles should be changed as soon as the recommended outlet pressure of 4 bar can no longer be maintained.

Routine Maintenance for the Mass spectrometer

Caution: Refer to the manufacturers guides supplied, for details of routine maintenance of third-party system components e.g. Rotary pumps, Turbomolecular pumps, Air Compressors, etc.

Planned maintenance

Many of the problems associated with poor instrument performance can be prevented with regular and effective maintenance. It cannot be stressed too strongly that two days service every six months will save time and increase sample throughput in the long term.

The main aim of routine maintenance is to rectify potential problems before they affect the accuracy of the instrument.

The following procedures should be carried out at intervals no greater than **six months**, unless a shorter time period is specified in the manufacturer's manual.

Change the Rotary Pump Oil

A rotary pump is a mechanical pump that relies heavily upon the performance of the oil to provide lubrication and cooling. The condition of the rotary pump oil will also directly affect the pumping ability of the rotary pump. In use the oil slowly breaks down, which in turn reduces pumping efficiency. New oil is a light brown colour, while old oil varies from dark brown to black. Oil which is cream coloured has been pumping a lot of water and the source of this water must be identified before resuming sample analysis. Running with old oil for extended periods of time will contaminate the analyser.

Note: New oil must be ballasted according to the manufacturer's instructions.

Note: Only use the oil specified by the manufacturer. Use of the wrong oil will result in decreased performance and possible damage to the pump.

The oil change procedure is detailed in the manufacturer's manual.

Change the Molecular Sieve in the Foreline Traps

The foreline trap fitted to the rotary pump contains molecular sieve, which traps oil vapour from the rotary pump and prevents it from contaminating the system, so to ignore this procedure will lead to a build up of hydrocarbons in the analyser.

The manufacturer's manual contains details of the procedure for replacement of the molecular sieve.

Follow the manufacturer's suggestions for replacement intervals.

Replacement of molecular sieve without venting the IsoPrime

It is possible to replace the molecular sieve in the foreline trap without venting the instrument by the following procedure.

Note: The whole operation must be performed within 5 minutes or the instrument must be vented.

1. Prepare the new charge of molecular sieve by drying thoroughly in an oven (see manufacturers manual for details).

2. Close the Nupro isolation valve on the IsoPrime.
3. Switch off the source.
4. Close the Speedivalve on the rear of the IsoPrime.
5. Switch off the rotary pump by the rocker switch on the side of the pump.
6. Vent the foreline by opening the purge valve fitted to the top of the foreline trap.
7. Remove the molecular sieve canister and replace the sieve according to the manufacturer's instructions.
8. Refit the canister and re-assemble the foreline trap.
9. Close the purge valve.
10. Switch the rotary pump on and allow it to pump for 1 minute.
11. Open the Speedivalve.
12. Observe the foreline pressure. A value of greater than 1×10^{-2} indicates a leak.
13. Observe the analyser pressure and turbo speed. When both have returned to normal values open the isolation valve.
14. Switch on the source.

Should it prove impossible to replace the foreline trap within 5 minutes, switch off the turbo and allow the instrument to vent. Complete the change of molecular sieve and pump down the instrument as normal.

Change Oil Mist Filter Elements

While this does not necessarily affect the performance of the instrument, changing the Oil Mist filters ensures that the environment the system operates in, is kept as safe as possible for the user.

Details of the procedure for replacement of the oil mist filters are given in the manufacturer's documentation.

Follow the manufacturer's suggestions for replacement intervals.

Compressor (if supplied) Maintenance

The performance of the instrument relies on the smooth running of the valves on the reference gas injector and the Gas Chromatograph. These are pneumatically operated, so the continued performance of the air compressor and airlines is important. The air compressor (if supplied with the instrument) should therefore be maintained in accordance with the manufacturer's guide supplied with it.

Compressed Air Water Trap Drainage

The compressed air water trap (if fitted) should be checked and drained two or three times weekly. Failure to do this may cause damage to occur to the Predyne valves used to operate the valves. Instructions for draining the water trap are included in the manufacturer's guide.

Mass spectrometer Repairs

Caution: Suitably qualified personnel only should perform maintenance operations. Please contact the Customer Service Department at Micromass or your local Micromass representative with any queries.

Overview

This section of the manual will deal with repairs to the system. Care must always be taken when removing items from the system to avoid damage and contamination. It is also advisable for the user to take notes, as the components are disassembled, to complement this manual during reassembly.

The components within the vacuum enclosure are very sensitive to contamination. Precautions must be taken to avoid introducing any contamination during maintenance procedures. It is advised that disposable gloves (unpowdered) be used when handling any of the components from within the vacuum enclosure. A single fingerprint within the vacuum enclosure may be sufficient to affect to operation of the instrument.

Remember: If there are any queries please contact the Customer Service Department at Micromass or the local Micromass representative.

Venting the Mass Spectrometer

Venting the mass spectrometer is basically the reverse of pumping the system down and the following procedure should be carried out:

1. Turn OFF the source using the option on the software.
2. If the ambient atmosphere contains a high level of moisture, it is advisable to connect a source of dry gas (high purity Helium, Nitrogen or dry air) to the outlet of the vent valve.
3. Switch OFF the turbo from the software. This turns off the turbomolecular pump controller.
4. Immediately after switching off the turbomolecular pump, close the backing line isolation valve.
5. The turbomolecular pump will now slow down and after approximately 5 minutes the pump will have reached 50% of full speed. At this point the vent valve will open and the system will come up to atmosphere, as shown by the Pirani gauge in the monitor window.
6. Isolate the mains power to the cubicle or disconnect the IEC connector. The various parts of the system can then be opened as required.

Removing the Ion source

Caution: Wear hand protection (gloves) for this operation to avoid contamination.

Source flange removal

The procedure for removing the source flange is as follows:

Caution: Care should be taken not to bend the feedthrough wires. Failure to follow this precaution may create vacuum leaks on the feedthrough.

1. Follow the procedure above and vent the mass spectrometer.
2. Remove the screws retaining the source connector cover and remove the source connector cover.
3. Disconnect the plugs labelled J1 and J7 from the system controller.
4. Unplug the two half plate leads from the source feedthroughs (labelled 1 and 4). Tuck the two half plate leads into the system controller.
5. Unplug the bakeout connections on pins 6 and 12 (where fitted). Tuck the leads into the system controller.
6. Using the extended 5mm ball-driver in the toolkit, undo the six bolts retaining the source flange to the vacuum housing.
7. If necessary use two of the mounting screws fitted into the jacking screw holes to loosen the flange.
8. Withdraw the source flange a short way and using the pliers from the toolkit, remove the bakeout connector wires on pins 6 and 12 (where fitted).
9. Remove the source flange. Ensure that the quad ring remains in its mounting groove.
10. Place the source flange on a clean lint free tissue on a flat work surface. Protect the sealing faces from abrasion.
11. Cover the open end of the analyser with a clean plastic bag to prevent ingress of contamination during maintenance.

Photo showing source connector cover

Photo showing source connection leads

Ion source removal

1. Using the pliers from the toolkit pull the gold push fit connectors from the feedthrough pins and push fittings on the source. Remove the filament connections first.
2. Support the ceramic inlet tube whilst retracting the spring-loaded probe into the inlet support. Remove the ceramic inlet tube, spring loaded probe and spring.
3. Undo the two screws holding the source to the source flange.

Photo of source mounted on source flange

Replacing the Ion Source

Caution: Wear hand protection (gloves) for this operation to avoid contamination.

Fitting the ion source to the source flange

The procedure for replacing the Ion source on the source flange is as follows:

1. Place the ion source into position on the source flange and secure with the two screws. Ensure that the front face of the source is parallel with the edge of the source flange.
2. Insert the spring into the inlet support and fit the spring-loaded probe. Withdraw the spring-loaded probe and insert the ceramic inlet tube into position in the side of the ion box. Ensuring a good seat in the ion box for the ceramic inlet tube, allow the spring-loaded probe to contact the other end of the ceramic inlet tube. A small twist of the probe should allow the ceramic inlet tube to mate correctly with the probe. If the fit is poor the source may need to be moved slightly along the ion path to allow the probe to align correctly.
3. Using the pliers from the toolkit refit the connecting wires. Follow the table below to identify which lead to use for each connection. The connectors with the small holes fit on the source and the large holes fit on the feedthrough. Ensure that all wires do not touch and are clear of all other metal components.
4. Check that the connecting wires are attached correctly and that there are no short circuits. Use a meter from the feedthrough pins to the appropriate source component to check continuity.

Photo of source connection points – right hand side

Photo of source connection points – left hand side

Table of source connection leads and connection points.

| Name | Length /mm | Source connection | Feedthrough pin | Type |
|------------------------|------------|-------------------|-----------------|-------------|
| Half plate 1 to flange | 70 | Half plate 1 | 1 | Kapton wire |
| Filament 1 to flange | 75 | Filament 1 | 2 | Bare copper |
| Filament 2 to flange | 65 | Filament 2 | 3 | Bare copper |
| Half plate 2 to flange | 95 | Half plate 2 | 4 | Kapton wire |
| Z1 to flange | 135 | Z plate 1 | 5 | Kapton wire |
| Trap to flange | 95 | Trap | 7 | Kapton wire |
| Ion repeller to flange | 60 | Ion repeller | 9 | Kapton wire |
| Ion box to flange | 100 | Ion box | 8 | Kapton wire |
| Z2 to flange | 135 | Z plate 2 | 10 | Kapton wire |

Source flange assembly drawing

Replacing the source flange

Caution: Cleaning solvents must not be used on Viton components as they may damage the Viton and be adsorbed. This results in poor vacuum whilst the Viton out-gasses.

Caution: Do not allow the sealing surface of the source flange to strike or rub the dowel pins. This will result in seal surface damage and a consequent vacuum leak.

The procedure for replacing the source flange is as follows:

1. Check that the sealing surfaces on the housing and the source flange are free of dust etc. If dust and fibres are adhering to the quad ring they may be removed by blowing with a supply of clean gas. A tissue soaked in acetone may be used to clean dirty sealing surfaces.
2. Offer the source flange to the housing. Connect the bakeout connections onto the feedthrough pins 6 & 12 (if fitted).
3. Align and engage the dowel pins with the holes in the source flange. Press the flange into position till it contacts the quad ring and hold in position.
4. Loosely replace the six bolts to hold the flange in position.
5. Tighten the mounting bolts in small amounts in the following order. Top centre, Bottom left, Top right, Bottom centre, Top left, Bottom right. Repeat this cycle until the quad ring is compressed and the flange contacts the analyser housing.
6. Reconnect the two plugs labelled J1 and J7 (J1 is closer to the source flange).
7. Reconnect the two half plate leads to pins 1 and 4.
8. Reconnect the two bakeout leads to pins 6 and 12.
9. Replace the cover and secure with the four screws.

Caution: Do not over-tighten the mounting bolts – the seal will not improve! If a vacuum leak is present it is necessary to remove the flange and check for damage to the seal surfaces or dirt on the quad ring.

Changing the Ion Source Filament

Caution: Wear hand protection (gloves) for this operation to avoid contamination.

Filament removal

The procedure for changing the Ion source filament is as follows:

1. Vent the instrument and remove the source flange.
2. Use the pliers from the toolkit to remove the filament connections and the trap connection.
3. Use the jeweller's screwdriver from the toolkit to remove the screw holding the heat conduction wire onto the top magnet assembly. Fold the wire out of the way of the magnet.
4. Undo the two screws that attach the top magnet holder to the defining slit holder and remove the magnet.
5. Undo the two screws that secure the filament support to the source block and remove the support and filament assembly.
6. Loosen the filament retaining screw from the support assembly, and remove the old filament.

Diagram of filament support assembly

Filament positioning

The procedure for positioning the Ion source filament is as follows:

Caution: The filament coating is very fragile. Under no circumstances should the coating be touched or the filament wire distorted in any way.

1. Before attaching the new filament, make sure that the filament wire is securely attached to the posts, and has no kinks or other defects. The coating should be smooth and even with no imperfections along the centre of the filament and the shield does not touch both of the filament legs.
2. Secure the new filament to the support assembly with the filament retaining screw. Ensure that the filament retaining screw is seated in the bottom of the slot on the filament.
3. Place the magnet/filament assembly on a flat metal surface.
4. Adjust the filament so that the wire is parallel to the metal surface by twisting it around the filament retaining screw.
5. Adjust the height of the filament wire to approximately 0.75mm from the flat surface. Once the filament wire is parallel to the flat surface and at the correct distance away, lock the filament in place by tightening the retaining screw.

Setting the height of the filament

Filament assembly

The procedure for assembling the Ion source filament to the source is as follows:

1. Use the jeweller's screwdriver from the toolkit to remove the screw holding the heat conduction wire onto the bottom magnet assembly. Fold the wire out of the way of the magnet.
2. Undo the two screws that attach the bottom magnet holder to the defining slit holder and remove the magnet
3. Undo the two screws that secure the trap support to the source block and remove the support and trap assembly. Note: The trap ceramic is loose and may fall out.
4. Attach the filament support assembly to the source. Tighten the two retaining screws evenly so that the assembly is parallel to the source block.
5. Looking up through the trap aperture in the source wraparound, observe the filament position in the electron entrance aperture. The filament should lie parallel to the front face of the ion box (ion exit slit face) and be positioned at the mid-point of the electron entrance aperture.
6. Tighten the two filament support retaining screws evenly and re-check the filament position.
7. Attach the trap support assembly to the source. Tighten the two retaining screws evenly so that the assembly is parallel to the source block.
8. Check that the trap ceramic is correctly positioned at the end of the trap. Check that the trap, trap ceramic and source wraparound fit correctly and no gaps are visible.
9. Use an electrical meter to check for filament continuity and for any short circuit between the filament and the source block.
10. Use the pliers from the toolkit to replace the filament connections and the trap connection.
11. The source flange is now ready for replacement in the analyser housing.

Filament position within electron entrance aperture

Disassembly of the Ion Source

Caution: Wear hand protection (gloves) for this operation to avoid contamination.

The procedure for disassembling the Ion Source is as follows:

Note: All items referred to relate to the numbered parts in the ion source assembly diagram.

Caution: The ion source is a complex precision engineered assembly. It contains over 100 components. Incorrect assembly will have a serious effect upon its performance. For ease of re-assembly it is strongly recommended that the components be laid out in the order that they are disassembled. The user may wish to make additional notes in the manual during the procedure for clarification of certain points.

Magnet, filament and trap removal

1. Vent the instrument and remove the source flange.
2. Remove the ion source from the source flange.
3. Place the ion source on a flat clean surface, with the source mounting bracket (item 1) down.
4. Use the jeweller's screwdriver from the toolkit to remove the screw (item 40) holding the heat conduction wire onto the top magnet assembly. Fold the wire out of the way of the magnet.
5. Undo the two screws (item 26) that attach the top magnet holder to the defining slit holder and remove the magnet assembly.
6. Remove the screw (item 40) holding the heat conduction wire onto the bottom magnet assembly. Fold the wire out of the way of the magnet.
7. Undo the two screws (item 26) that attach the bottom magnet holder to the defining slit holder and remove the magnet assembly.
8. Undo the two screws (item 43) that secure the filament support to the source block and remove the support and filament assembly.
9. Undo the two screws (item 43) that secure the trap support to the source block and remove the support and trap assembly. Note: The trap ceramic is loose and may fall out.

Stack disassembly

Caution: The source assembly jig must be used for both the assembly and disassembly operations on the source. Failure to use the jig will result in metal wipes along the ceramic rods, which will provide a conductive path and promote flashover. This may render the source inoperative.

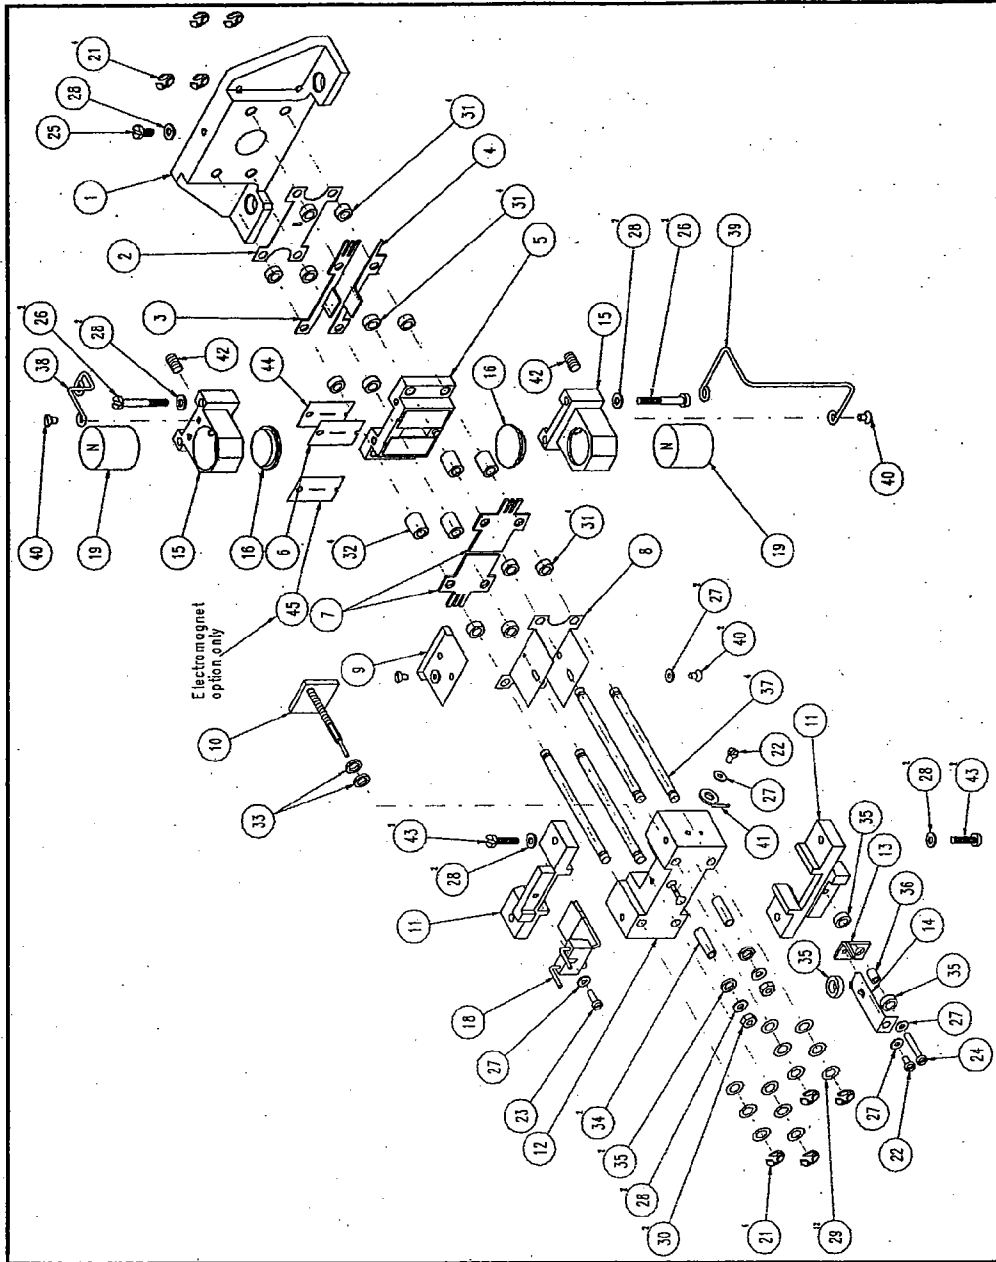

Caution: Ceramics are fragile and may be easily broken. Use caution and do not subject the ceramics to any shearing or twisting forces.

The procedure for disassembling the stack is as follows:

1. Rest the source on the mounting bracket so that the ion box is uppermost. Using the pliers from the toolkit, remove the circlips (item 21) from the ceramic rods (item 37).
2. Lift off the wavy washers (item 29), noting the number used.
3. Remove the ion box assembly from the ceramic rods.
4. Remove the four ceramic spacers (item 31).
5. Lift off the two half plates (item 7).

IsoPrime-EA User Manual

6. Fit the source assembly jig over the ceramic rods so that the protruding ceramic tubes of the jig contact the ceramic spacers (item 32).
7. Invert the source and jig so that the source mounting bracket is uppermost.
8. Remove the circlips from the ceramic rods.
9. Lift off the source mounting bracket. Note: Use care to ensure that the ceramic rods do not lift out when removing components from the source assembly.
10. Remove the alpha plate (item 2).
11. Lift off the four ceramic spacers (item 31).
12. Remove the z plates (items 3 & 4).
13. Lift off the four ceramic spacers (item 31).
14. Remove the source slit support (item 5).
15. Lift off the four ceramic spacers (item 32).
16. Remove the four ceramic rods (item 37) from the assembly jig.
17. Remove the source defining slit and support plate (if fitted) (items 6&44 or item 45) from the source slit support by sliding them out of the holder.

Ion source assembly diagram

Note: The columns Qty. PM and Qty. EM refer to the number of each item used within the ion sources for permanent magnet and electromagnet instruments respectively.

Disassembly of the ion box

The procedure for disassembling the ion box is as follows:

1. Remove the screw and washer (items 40 & 27) holding the filament shield (item 9) in position. Remove the filament shield.
2. Remove the screw and washer (items 40 & 27) on the other side of the wrap around (item 8). Remove the wrap around from the ion box.
3. Undo and remove the two set of nuts and washers (items 30 & 28) that retain the ion repeller in the ion box.
4. Lift off the ceramic (item 35).
5. Remove the ion repeller from the inside of the ion box.
6. Lift off the ceramics (items 35 & 34) from the ion repeller legs. Note: On some sources the ceramic (item 34) may be in two pieces.
7. If required, remove the bolt and screw (items 22 & 27) securing the terminal washer (item 41) to the source.

Diagram of ion box assembly

Dismantling the trap assembly

The procedure for dismantling the trap assembly is as follows:

1. Remove the trap ceramic from the trap (item 35) if it has remained in position.
2. Remove the screw and washer (items 22 & 27) that hold the trap to the trap bracket and remove the trap.
3. Remove the screw and washer that hold the trap bracket to the support block. Lift off the ceramics (items 35 & 36).

Diagram of trap assembly

Dismantling the magnet assembly

Caution: Magnets are brittle. Do not allow magnets to come together or contact magnetic materials under their own attraction. This may result in chipped or broken magnets. Damaged magnets will affect the operation of the source.

The procedure for disassembling the magnet assembly is as follows:

1. Prise the pole shoe from the end of the assembly.
2. Remove the grub screw (item 42) from the magnet housing.
3. Remove the magnet slug from the housing. Note the magnet orientation.

Assembly of the Ion Source

Caution: Wear hand protection (gloves) for this operation to avoid contamination.

The assembly of the ion source is largely the reverse of disassembly. Once assembled the source should be checked using a continuity to ensure that all plates are isolated and that the filament is not shorting. If available a Megger or other high voltage continuity tester should be used to check for shorts.

Folding photo-etched components

Because of the fragile nature of some of the components of the source it is impossible to supply them in a form ready for assembly. These photo-etched components are supplied flat for ease of packing and to limit the possibility of damage. The procedures below describe how to fold new photo-etch into the form in which it is used within the source.

Trap

The procedure to fold a trap from new photo-etch is as follows:

1. Using the pliers from the toolkit fold the two ears on the trap by gripping the ears and folding them so that the etch line is on the inside of the fold. Make a 90° bend.
2. Push the central finger up from the trap. Do not push the finger too far. Use the trap ceramic (item 35) and bend the finger to allow the ceramic to fit and be held in position by the finger.
3. Using the pliers from the toolkit fold the tab at the end of the trap. Ensure a clean straight fold of 90° perpendicular to the long axis of the trap.

Diagram of folded trap

Source wrap-around

The procedure to fold a source wrap-around from new photo-etch is as follows:

Note: this procedure is best performed before starting any assembly of the source.

1. Using the back of the ion box as a pattern, sandwich the new photo-etch between the ion box and the side of the source assembly jig. Use two ceramic rods (item 37) inserted through the ion box as alignment guides. Ensure that the etched fold lines will be on the inside of the fold.
2. Position the first edge to be folded next to an edge of the assembly jig. Fold the side into position along the slot in the ion box. Using a clean stainless steel rod or the back of a scalpel, rub along the folded edge to ensure that it is folded correctly.
3. Rotate the ion box assembly and align the other fold with the edge of the assembly jig. Repeat the folding procedure as before.
4. Remove the ceramic rods and turn the ion box and wrap-around over. Check that the wrap-around is lying flat across the whole of the face of the ion box. Pay particular attention to the fold regions and look for any distortion across the corners where the ceramic rods fit.
5. Remove the wrap-around from the back of the ion box. The wrap-around is now ready for use.

Diagram of folded source wrap-around

Filament shield

The procedure to fold a filament shield from new photo-etch is as follows:

1. Using the assembly jig, align the filament shield photo-etch on the assembly jig so that the long etch line lies along an edge.
2. Use a steel ruler to sandwich the filament shield onto the block.
3. Fold the edge of the filament shield over the assembly jig so that the etch line is on the inside.
4. Use a stainless steel rod or the back of a scalpel to rub the fold down and form a 90° bend.
5. Using the pliers from the toolkit fold the ears through 90° to form the filament shield as shown in the diagram below.

Diagram of folded filament shield

Reassembling the ion box assembly

The procedure for assembling the ion box assembly is as follows:

1. Refit the terminal washer (item 41) using the bolt and washer (items 22 & 27). Ensure that the tag points to the rear of the ion box as shown in the assembly diagram and protrudes at an angle of 45°.
2. Place the ceramics (items 35 & 34) onto each leg of the ion repeller. Ensure that item 34 fits within item 35.
3. Place the ion repeller in the ion box.
4. Place the ceramics (item 35) over the ion box legs and ceramics (item 34).
5. Fit the washers (item 35) and nuts (item 30) to the legs of the ion repeller.
6. Tighten the nuts carefully. Note: Over-tightening the nuts may break the ceramics.
7. Fit the wrap-around oriented so that with the tapered hole for the inlet probe is on the left of the ion box, the legs of the ion repeller are facing you the electron entrance hole (square) is on the top of the ion box.
8. Check that the wrap-around is lying flat against the front face of the ion box.
9. Fit the two screws and washers items 40 & 27) that hold the source wrap-around in position till they hold the wrap-around loosely in position.
10. The ion box assembly is now ready for assembly into the source stack.

Diagram of ion box assembly

Reassembling the trap assembly

The procedure for assembling the trap assembly is as follows:

1. Mount the trap bracket on the support using the ceramics (items 35x2 & 36) and the mounting screw and washer (items 24 & 27).
2. Fit the trap to the trap bracket using the bolt and washer (items 22 & 27).
3. Fit the trap ceramic (item 35) to the trap and if required adjust the central finger of the trap to hold the ceramic in position.

Diagram of trap assembly

Reassembling the magnet assembly

Caution: Magnets are brittle. Do not allow magnets to come together or contact magnetic materials under their own attraction. This may result in chipped or broken magnets. Damaged magnets will affect the operation of the source.

The procedure for assembling the magnet assembly is as follows:

1. Insert the pole face (item 16) into the magnet housing (item 15) and support so that the pole face lies flat against the face of the housing.
2. Insert the magnet slug (item 19) in the correct orientation (shown on the drawing) till it contacts the pole face.
3. Secure the magnet using the grub screw (item 42). Note do not over-tighten the screw or the magnet may be damaged.

Reassembling the stack

Caution: The source assembly jig must be used for both the assembly and disassembly operations on the source. Failure to use the jig will result in metal wipes along the ceramic rods, which will provide a conductive path and promote flashover. This may render the source inoperative.

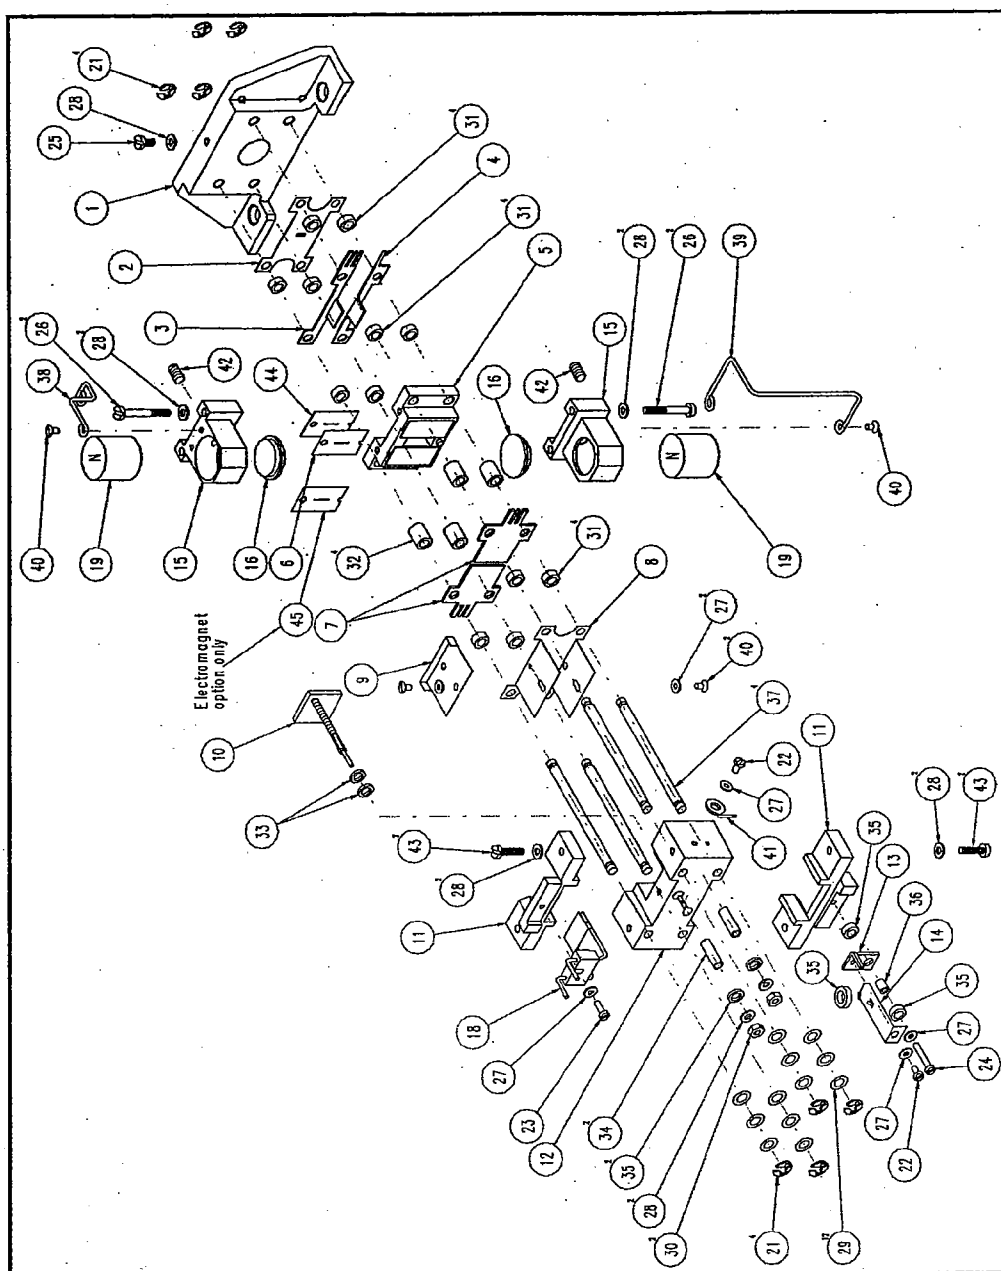

Caution: Ceramics are fragile and may be easily broken. Use caution and do not subject the ceramics to any shearing or twisting forces.

The procedure for reassembling the stack is as follows:

1. Place the assembly jig on the bench with a long side facing you and with the protruding ceramics uppermost. The face nearest you will become the trap side of the source (bottom) and the opposite face the filament side (top). The source is assembled from the middle to the ends to reduce the chance of metal wipes on the ceramics. The front of the source will be assembled first (toward the source mounting bracket).
2. Place the four ceramic rods (item 37) in the assembly jig.
3. Place the four ceramic spacers (item 32) on the rods.

IsoPrime-EA User Manual

4. Insert the source defining slit and support plate (if fitted) (items 6 & 44 or item 45) to the source slit support by sliding them into the holder. Note: The defining slit (item 6) should be closest the retaining plates of the support. The etched numbers on the defining slits should be visible. The slits should engage fully on the dowel in the support.
5. Replace the source slit support (item 5). Orient the support so that the raised section points down between the ceramics (item 32) and so that the dowel in the source slit support is closest you (the bottom).
6. Replace the four ceramic spacers (item 31).
7. Replace the z plates (items 3 & 4). Item 4 (z plate with only one finger) fits on the bottom two ceramic rods with the tab towards the centre of the source stack and pointing down. Item 3 (z plate with three fingers) fits on the top two ceramic rods with its tab facing the other z plate and pointing down.
8. Replace the four ceramic spacers (item 31).
9. Replace the alpha plate (item 2).
10. Replace the source mounting bracket.
11. Replace the circlips onto the ceramic rods.
12. Invert the source and jig so that the assembly jig is uppermost. Note: Do not allow the ceramic rods to slide out of the stack during the inversion process.
13. Remove source assembly jig from the ceramic rods.
14. Replace the two half plates (item 7).
15. Replace the four ceramic spacers (item 31).
16. Replace the ion box assembly on the ceramic rods.
17. Replace the wavy washers (item 29), using the number used previously.
18. Compress the source stack downwards and fit the circlips on the ceramic rods. It may be necessary to adjust the number of wavy washers if new components have been used in the assembly. The source stack should be held firmly together from the tension of the wavy washers on the circlips.
19. Ensure that the source wrap-around is fitted snugly to the ion box and tighten the retaining screws (items 40 & 27).
20. The stack assembly is now complete.
21. Refit the other source components as detailed under 'Changing the ion source filament'.

Penning Gauge Maintenance

Please refer to manufacturer's guide supplied and the cleaning procedure below.

Cleaning Procedures

This is a generalised cleaning procedure for both ceramic and stainless steel components used in the source. If more details are required then please contact Micromass UK Ltd Customer Service Department or the local representative.

Caution: Some of the components used within the IsoPrime are fragile and care must be taken when cleaning to avoid damage. Note: The filament should not be cleaned under any circumstances.

Warning: The cleaning procedures involve the use of boiling water and strong chemicals. It is important that the user assess the risks involved in the use of these materials before use.

Rough Cleaning

Polaris Powder (Al_2O_3 powder) or Scotchbrite can be used to remove obstinate marks (burn marks, etc.).

Note: When cleaning the ion repeller use metal polish to avoid scratching the surface. The ion repeller should have a mirror polish finish.

Pre-cleaning

For stainless steel components immerse in hot solvent cleaner in ultra-sonic for 30 minutes or hot ultra-sonic wash in Decon 90 (or similar aqueous cleaner) for 15 minutes followed by a rinse in de-ionised water. Either of these processes should remove any fingerprints and mild contamination.

For ceramic components immerse in boiling in Decon 90 (or similar aqueous cleaner) for 30 minutes followed by a rinse in de-ionised water.

Final Cleaning

This is a generic cleaning procedure for any component that can withstand the conditions. Exceptions include Nylon, O-rings, Kel-F, etc.

1. Immerse in a clean container with high purity Acetone. Place in an ultrasonic bath and leave to clean for 15 -20 minutes.
2. Boil in de-ionised water for 30 minutes.
3. Change the water and boil for a further 30 minutes
4. Dry in oven at 100 to 120° C for 12 hours.

After cleaning all components should only be handled using gloves.

If the flight tube requires cleaning, chemical cleaning alone is rarely sufficient.

Please, follow the procedure outlined below:

1. In the first instance, the flight tube needs to be scrubbed with a wire brush, paying particular attention to any burn marks at the entrance of the tube.
2. Wash off all the solid residues with plenty water.

IsoPrime-EA User Manual

3. Boil for 30 minutes in deionised water.
4. Rinse with high purity Acetone
5. Ultrasonic for 15-20 minutes in high purity Acetone.
6. Rinse once more with Acetone.
7. Dry in the oven at 120° C for 2 hours.

Penning gauge cleaning

1. Remove the electronic podule carefully.
2. Using a proper circlip tool, remove the circlip from the tube.
3. Carefully, pull out the cathode cup and the cathode plate.
4. Use an AIM spanner to undo the clamp collar from the other end of the tube.
5. Pull the anode assembly without twisting the anode.
6. Remove the O-ring.
7. Use an ultrasonic tank to clean all the above components with a proper diluted solvent for about 10 minutes. Repeat the process with alcohol for 5 minutes.
8. If necessary use a very fine emery paper to clean the gaps between the strikers and the shield disc.
9. Adjust the gap between the strikers and the shield disc by bending the striker (not the shield disc). The gaps between the striker and the shield disc should be maintained between 0.25 to 0.35 millimetres.
10. Re-assemble the electrodes in the tube in the same way as indicated in the AIM gauge's instruction manual.

Rotary Pump Repair

Please refer to manufacturers guide for details.

Turbomolecular Pump and Vent Valve Repair

Please refer to manufacturers guide for details.

Air Compressor (if supplied) Repair

Please refer to manufacturers guide for details.

Electronics Repair

Caution: Suitably qualified personnel only should perform maintenance operations. Please contact the Customer Service Department at Micromass or your local Micromass representative with any queries.

Removal of the system controller

1. The main electronics for the IsoPrime is located in the right hand side of the IsoPrime cubicle.
2. It is recommended that the IsoPrime be vented before replacing this unit otherwise the following steps must be completed within 5 minutes.

IsoPrime-EA User Manual

3. Remove IEC connector to the Electronics unit (and the IEC connector to The bakeout supply if fitted) and all connectors to the unit including the two 6W QM connectors underneath the HV shield at the top of the instrument. Disconnect the two half plate leads (and bakeout leads if fitted) from the analyser and push them back in the hole of the electronics box.
4. Undo the screw at the front of the electronics unit.
5. Pull handle to the left to clear the door and pull out.

Photo of system controller removal (bakeout supply shown fitted)

Refitting the system controller

1. Ensure that the half plate and bakeout leads are pushed inside the electronics unit
2. Push in the electronics unit
3. Retrieve the half plate wires and bakeout cables from inside the unit and connect to the correct pins on the analyser (see label on the instrument). Refit the two 6W rectangular QM connectors ensuring that all the wires mate properly with the pins on the analyser
4. Refit the HV shield
5. Screw in the screw at the front of the electronics (note the box may have to be moved around until the screw locates in the hole)
6. Refit all cables except the IEC lead.
7. Note J2 is only used if an electromagnet is fitted.
8. J5 is used for interfaces requiring extra valves i.e. the Trace gas preconcentrator
9. J6 is the standard valve connector for controlling RG etc.
10. Refit the IEC plug.

Diagram of system controller front panel layout

Removal of the bakeout power supply

1. Remove Electronics unit with bakeout unit attached as described in the previous section
2. Undo the 4 screws that hold the bakeout supply onto the electronics box.
3. Pull the two wires through the electronics box

Photo of removal of bakeout supply

Replacement of the bakeout power supply Ensure the blanking plug is replaced with the grommet (this will involve removal of the lid of the electronics box.

1. Ensure that the bakeout supply is set to the correct voltage.
2. Push the two wires through this hole
3. Screw the bakeout unit to the electronics box using the four screws
4. Replace the electronics unit into the IsoPrime as described in the previous section.

Removal of the electromagnet power supply

Remove the lower blue cover by pulling the top forward and then lifting the cover out of the mounting slots.

Remove IEC connector at the back of the electromagnet PSU

Photo of rear connections on electromagnet power supply

Remove the 4 screws that hold the power supply in position

Photo of electromagnet power supply mounting

IsoPrime-EA User Manual

Pull the power supply forward

Remove the 15W D connector

Remove XLR connector by pushing the button in and pulling the connector out

Replacement of the electromagnet power supply

1. Check the Voltage Selector is set for the correct supply
2. Refit the XLR Connector
3. Refit the 15W D Connector
4. Push unit back into the metalwork
5. Screw in the 4 screws
6. Reconnect the IEC mains connector

See setting up the Electronics in the using a terminal emulator section if this is a new addition to your IsoPrime

Removal of the head amplifier

1. Turn off source
2. Remove the 5 W Din connector
3. Remove The 4 fibre optic cables
4. Undo the two hex screws holding the unit on

Photo of head amplifier removal

Replacement of the head amplifier

Using a suitable metal implement, short the feedthrough pins to the metal of the analyser

Photo of shorting of head amp feedthrough pins

Slide the head amp over the dowels

Screw up the two hex screws

Replace the 5W Din connector

Replace the fibre optic cables

Note From Top to Bottom they go in the order 3, 2, 1, 4. The very top one is not used.

IsoPrime user replaceable fuse information

Note: In all applications using two fuses, for maximum reliability replace **both** fuses if one fuse has blown.

Mains inlet to IsoPrime

Computer, Monitor and Printer Repair

Please refer to manufacturers guide for details.

Routine Maintenance for the EA

Routine maintenance of the elemental analyser is generally associated with replacement of consumable such as oxidation, reduction, absorbent filter tubes, along with their relevant packing materials. In addition the build up of ash in the combustion tube needs to be controlled. Detailed aspects of these and other less frequent maintenance considerations are detailed in section 5 of the elemental analyser user manual.

Caution: Before carrying out any operation which involves breaking the flow of helium to the mass spectrometer close the Nupro isolation valve to the mass spectrometer.

Cutting vitreous silica capillaries

Using the ceramic capillary cutter supplied with the toolkit, scratch the surface of the polyimide at right angles to the capillary. Ensure that the capillary does not break or smash at this stage, otherwise glass dust will result, thus forming active sites where the chromatography may degrade.

When the scratch has been made, bend the capillary gently, until it breaks off.

Cuts, performed in this manner, are usually clean. It is, however, advised to inspect the cut using a magnifying glass. Inspection at this stage takes only a few seconds, it could take a significant length of time to diagnose the problem site, later on, when the entire system has been assembled together.

Replacing the reference capillary

The reference line capillary should never require changing. However it may be broken accidentally in which case the following procedure should be carried out.

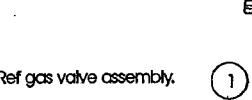

Note: This procedure assumes the sample line is connected to the splitter tee and the flow of sample line helium through the splitter into the mass spec registers between 2 and 4E-6mb.

1. Close the Nupro isolation valve.
2. Switch off the source.
3. Remove the old capillary from the 1/16th tee connecting it to the 1/16th by 0.020" stainless steel capillary leading to the Nupro valve.
4. Remove the old capillary from the reference open split line.
5. Cut 2 metres of 75um fused silica quartz capillary.
6. Push one end of the glass capillary through the tee into the stainless steel capillary leading to the Nupro valve a distance almost but not quite up to the Nupro valve itself.
7. Fix the capillary along with the one coming from the prep system to the tee with a 1/16th SSUT nut and GVF(2) 004 ferrule.
8. Engage the other end of the capillary a distance of 50cm minimum into the reference line open split.
9. Open the Nupro valve check the penning gauge reading is in the region of 2-4E-6mb. If it is much greater then suspect that the GVF 004 ferrule is not tight enough.
10. Switch on the source and check for leaks, initially monitoring the background nitrogen. A virtual leak such as out-gassing associated with the new capillary will soon decay
11. Open the reference gas valve and introduce CO₂. Tune the source to CO₂ and measure the transport time associated with the new capillary. This time should not differ greatly from the previous capillary.
12. Carry out reference gas stability tests on both CO₂ and N₂ until the system stabilises.

STEP 1. Fitting the vitreous silica capillary.

STEP 2. Ref gas valve assembly.

The reference gas assembly is re-built according to the diagram shown above. Additionally, take the following precautions:

- Ensure that the RG valve is OPEN whilst performing this operation, otherwise, damage may result to the valve needle.
- Ensure that the 25 μ m capillary (25 μ m x 350 μ x 7cm) does not protrude beyond the flat face of the GVF 003/004 ferrule. This ferrule has been especially drilled, to allow the capillary to engage into the conic section up to approximately 1mm from the flat face. Provided that the capillary has an OD greater than 0.3 mm, it will be impossible for it to pass through to the upper face.
- Ensure that the 25 μ m capillary is cut clean. Please inspect the cleanliness of the ends, using a magnifying glass.
- Ensure that the stainless steel capillary, labelled with the number 6 on the diagram above, is not engaged into the tee union, beyond the start of the tee inlet port. If this is allowed to happen, the flow of Helium gas will be adversely impeded at this site.
- Ensure that all the other stainless steel capillaries are mounted in their respective connectors with the minimum of dead volume. That is, they should all be butt mounted.
- Leak check the entire assembly thoroughly, after re-assembly has been completed. Please refer to the subsection titled Cleanliness of the vacuum and leak checking.

The MOVPT valve

This is a very robust valve, however, on rare occasions it is possible that it develops a leak between the pneumatic head and the valve body. A schematic of this valve, as supplied by SGE, the manufacturers of the valve, is included below.

- | | |
|-------------------------|-----------------------|
| 1. Pneumatic Head Cap | 2. Piston spring |
| 3. Piston Plunger shaft | 4. Skirt seal |
| 5. BN16 nut | 6. GFF-16 ferrule |
| 7. Pneumatic body | 8. "O" ring seal |
| 8a. Flat MOVPT washer | 9. MVTL seal spring |
| 10. Thrust tube | 11. PTFE Shaft seal |
| 12. Brass union | 13. Star washer |
| 14. Lock nut | 15. Lower stem |
| 16. SN-16 nut | 17. VSR-16 ferrule |
| 18. Stem body | 19. Vespel valve seal |
| 20. SS union | 21. GFV004 ferrule |
| 22. SN-16 nut | |

The cause for the leak mentioned above is the PTFE shaft seal, designated by the item number 11. Please, replace this seal, according to the diagram supplied.

The MCVT-1 splitter valve

This valve is very robust in operation and will rarely need attention. However, it can develop a leak on the PTFE seal to atmosphere. A schematic of this valve, as supplied by SGE, gives a clear description of the replacement procedure.

- | | |
|----------------------|-----------------------|
| 1. Control knob | 2. Needle |
| 3. Upper assembly | 4. Compression spring |
| 5. Thrust tube | 6. Thrust tube stop |
| 7. Thrust tube | 8. PTFE seal |

| 15. Valve body | 16. Valve seat |
| 17. SS Union | 18. ferrule |
| 19. 1/16th capillary | 20. Nut |
| 21. Nut | |

Changing Gas Bottles

Helium

Caution: The Nupro isolation valve must be closed whilst changing the Helium gas bottle. The EA TCD filament must be switched off and the bottle must be changed as quickly as possible to protect the EA combustion and reduction tubes.

After changing the Helium gas bottle, please, take the following precautions:

- Leak check the connections you have disturbed at the gas supply bottle regulator, using Snoop, or some other leak checking solution.
- Check that the gas supply pressure at the bottle is set to 4 bar.
- Allow all the gas lines to purge for several minutes, prior to re-opening the isolation valve.
- Take all the necessary precautions, as the isolation valve is re-opened as described in section 6, the section on setting up the reference gas injector.

Reference gas

Unlike the replacement of Helium, it is not necessary to close the isolation valve, whilst changing the reference gas bottles.

After the bottle has been changed, the entire gas lines must be purged to eliminate all traces of atmospheric gases. This is best achieved by opening fully the needle valve that controls the flow of gas at the reference gas purge outlet.

Leave the needle valve fully open for a few minutes, then reduce the flow to 5 ml min⁻¹.

Fault finding

This section has been included in order to help the user diagnose the source of a fault, should a problem be encountered. It can only be expected to serve as a guide rather than a complete description of all situations that may arise as the instrument is used. It may be worthwhile to keep a record of any experiences, if it is felt that any information gathered in this way is of general interest and should be included in future versions of this manual, please, contact the customer service department at Micromass UK Ltd.

I cannot achieve the recommended operating pressures

On the Pirani gauge

The normal operating reading on the Pirani gauge is 10^{-3} mbar. After breaking vacuum it may take some time to reach this pressure, in particular if the atmospheric moisture levels were high at the time that the analyser was open to atmosphere. It could take one day to return to 10^{-3} mbar. If this cannot be achieved, then:

- Check for leaks with Acetone.

Caution: Never use Acetone on a Viton seal. Never use water to leak check.

If Acetone is applied at a leaking site, at first, the Pirani reading may decrease. The liquid Acetone, in this instance forms a temporary "plug" for the leak, thus causing the Pirani reading to fall. This is then followed by a sharp rise in the Pirani reading, as the Acetone is sucked into the vacuum enclosure through the leaking site. such behaviour is positive identification of a leaking site; The leak must then be cured, either by tightening the connection, or by replacing the seal at this connection.

- Check for vent valve leakage.
- Check that the foreline trap is not saturated and requires new molecular sieve.
- Check the operation of the Rotary pump.

On the Penning gauge

The Penning gauge will not reach its normal operating pressure if

- There is a leak on the mass spectrometer vacuum enclosure.
- There is a high content of atmospheric gases drawn into the mass spectrometer via any of the inlet capillaries.
- Helium is not flowing out of either the reference or the sample open split (Check the Helium supply bottle)
- The Turbomolecular pump is in Stand-by.
- The Turbomolecular pump is faulty and not pumping efficiently.
- The Penning gauge or its supply control unit is faulty. Note: If the vacuum reading is too low then the Penning gauge probably needs cleaning.

I cannot achieve the recommended background levels

For Argon

A normal background for Argon should be better than $1\text{E-}11$ A. If this is not achieved, then this is indicative of a leak from atmosphere. The leak (leaks) must be located. The most efficient way to locate such a leak is to use Argon. Please refer to the subsection titled Cleanliness of the vacuum and leak checking in section 6, where the procedure is fully described. It must be remembered that ingress of atmospheric gases can occur anywhere as far as the gas supplies bottles, and it is not always sufficient to leak check around the mass spectrometer and the elemental analyser.

The purity of the gases specified (both He and CO_2) is such that the levels of Argon in these gases is insignificant, and should make only a small contribution to the background levels, well below the normal operating levels.

On extremely rare occasions, it has been observed that some of the supply gases may contain Argon well in excess of the suppliers specifications. This is a very, very rare occurrence, but one that cannot be ruled out completely. Should such a situation arise, then the Argon background may well exceed the normal operation level, although no leak is present.

In this most unlikely event it can only be identified by actually swapping the bottle itself.

CO_2 and N_2

The normal operating background levels for CO_2 and N_2 , should not exceed $5\text{E-}11$ A, with the elemental analyser combustion and reduction tubes set to temperature.

If background levels, exceed this value, then it is most likely caused by outgassing of contamination within the combustion and reduction tubes soon after they have been changed. The backgrounds in this case should drop to normal in about 1 hr.

The background scan is dirty

With prolonged use, the ion optics enclosure may become contaminated. This can be detected by performing background scans.

As long as a reasonable mass spectrometer peak shape is retained, and the quality of data is not affected in anyway, then no action should be taken.

However, if the contamination present in the vacuum enclosure, affects the quality of the results, then the Ion source, the flight tube the source and collector housings must be thoroughly cleaned. Please, refer to the Mass Spectrometry repairs section. This section describes how to carry out various repairs to the mass spectrometer.

I cannot operate the valves

The most common reasons are:

- The compressed air supply is at the wrong pressure.
- There is no compressed air reaching the valve heads.
- The valve cable is disconnected.
- The valve cable is connected to the wrong socket. J5 is for Trace gas preconcentrator only. All other prep systems connect to J6.
- The solenoid valve, corresponding to the valve being actuated, is faulty
- The valve drive board inside the system controller is faulty.

I cannot get a good mass spec peak shape

Any of the following conditions would cause a poor mass spectrometer peak shape:

- Contamination in the Ion Source.
- Contamination in the flight tube.
- Poor source tuning parameters.
- Wrong location for the magnet.
- Faulty source controller unit.

I cannot get stability

The reference gas pulses have an abnormal shape

Degradation in the shape of reference pulses has several causes, almost all of these, require that the reference gas injector be re-built. Please refer to this subsection earlier in this section.

The following list indicates how problems may arise within the reference gas injection assembly:

- The GVF 003/004 ferrule, which constitutes the seal for the ON/OFF action of the MOVPT valve, is of a relatively soft material. This valve is used intensively and after prolonged usage, the sealing face of the ferrule becomes damaged. It needs to be replaced.
- The 25 μ m capillary used to inject the CO₂ gas into the reference flow of Helium, is becoming partially blocked with ferrule or glass dust and needs replacing.
- If instability has occurred, immediately after the reference gas injector has been rebuilt, then check that the correct size capillary has been used, that the 0.006" stainless steel capillary, has been mounted back into the assembly, and that all the recommendations described in the Rebuilding the reference gas injector section have been observed.
- Check that there are no leaks at any of the connectors within the entire assembly.

The reference gas pulses have a normal shape

Please make the following checks:

- Have the elemental analyser combustion tubes been changed recently. If so wait one hour after temperatures have been attained before carrying out a sequence of stability tests.
- Using Argon, leak check the entire system.
- Check that the mass spectrometer is tuned correctly, in particular that the HT is centred on the mass spectrometer peak shape.
If the ambient temperature changes significantly, it is possible to drift off peak centre. This is a very common cause for instability.
- If the mass spectrometer has recently been switched off, please, allow at least one hour for all the components, to stabilise.
- If the vacuum enclosure has recently been exposed to atmospheric gases, then it may take up to one hour for stability to be achieved on the reference gas ratios. This is usually indicated by steadily falling ratio values
- Check the long term stability of the ratios by performing a time scan of the ratios. Please refer to section 6. which describes how to monitor the mass spectrometer stability. The long term behaviour of the ratio trace is very indicative of the reason for mass spectrometer instability.
The ratio trace obtained may display any of the following characteristics:
 - Steady noise band, in excess of $\pm 0.1\%$.
The problem is most likely, an electronics fault:
 - Source supplies are unstable
 - HT supply is unstable
 - Head Amplifier is unstable

It is advisable to contact the customer service department at Micromass

- Random glitches on an otherwise steady noise band indicate, a source filament problem.
- The ratio trace has a slow sinusoidal shape. This is normally indicative of a pumping problem.
- Air conditioning affecting net gas capillary.

I cannot get linearity

- A trivial cause

An apparent 'non linear' effect is sometimes reported.

If the reference gas, which is being used to test the linearity of the system is contaminated by a constant source of contaminant, then depending on the pressure of the reference gas the contamination will be more or less significant. We are therefore concerned with contamination occurring beyond the reference gas pressure regulator.

Apart from leaks of atmospheric gases at the various connectors, the most common source of contamination is a leak between the pneumatic head and the body of the reference gas valve.

A leak at this site can occur in one of two ways:

- The seal between these two compartments is leaking. See the subsection Rebuilding the reference gas injector earlier in this section.

IsoPrime-EA User Manual

- The compressed air pressure exceeds the recommended value.

Important note: Please check that the non linearity effect observed is not caused by the phenomenon described above.

If the cause of the non linearity is not certain, the customer service department at Micromass UK Ltd MUST be contacted.

I cannot get precision on the EA

Ensure that the system is both stable and linear, using the stability and linearity tests described in section 6.

- The elemental analyser combustion/reduction tubes may need regenerating or replacement. The elemental analyser water trap may need regenerating. The combustion tube may contain too much ash.
- The tin sample capsules may contain variable amounts of organic contaminants. This shows as variable CO₂ yield on the blank samples.
- The method file timings are not optimum.
- Check for leaks within the EA and all interfacing connections

I cannot get accuracy

Ensure that the system is both stable and linear and that there is precision of measurement on a standard material

The inaccuracy is constant across a variety of standards

- Check the reference gas calibration.
- Check that there are no leaks within the reference gas assembly.
- Check that there is a continuous flow of CO₂ gas through the reference gas purge. If no flow is recorded, then, please purge the CO₂ line with a high flow initially, then reducing this flow to 5 ml min⁻¹ as described in section 6.
- Check for possible contamination in the EA and all interfacing lines.

The inaccuracy is random across a range of standards.

- The combustion tube needs regenerating or the ash removed.
- The chemical water trap needs regenerating
- Check the cleanliness of the EA and all interfacing capillaries and connectors.
- Check for possible leaks within the EA

I have poor sensitivity

Sample sensitivity is poor, reference gas sensitivity is OK

The mass spectrometer is not responsible for the loss of sensitivity in this case. The problem resides with the EA or its interface.

- Firstly, check for leaks, at all the connections within the EA.
- Loss of chromatography related to dead volumes.

Both sample and reference gas sensitivities are poor

The problem resides with the mass spectrometer. There are very many possible reasons for this and only the most common causes can be described here. If the problem is not rectified, please, contact the customer service department at Micromass UK Ltd stating clearly all the checks that have been made

- Check the source tuning parameters
- Check the mass spectrometer peak shape.
- Check that the Source Electronics respond correctly to the software inputs i.e. Alter the value of each parameter in turn from the data system and check that the values shown on the analogue dials on the front of both the source controller and the source electronics, correspond to the values that have been selected in the tune source parameters window.
- Other causes arise from poor source filament position, deterioration of the source filament, and inefficient pumping.

Sample sensitivity good, Reference sensitivity poor

- Blockage in the reference line.
- Contaminated reference gas
- Too much interface helium flowing in the reference gas box.

I have no sample peak

No sample peak on MS and no signal when RG is open

The problem here is obviously with the mass spectrometer. There are multiple reasons:

- The isolation valve is closed
- The source is not switched ON.
- The mass spectrometer is not tuned to CO₂.
- The wrong tuning file is loaded.
- The magnet supply is not turned ON or is faulty.

If after checking these points there is still difficulty, please, contact the customer service department at Micromass UK Ltd.

No sample peaks on MS, Ms OK, no sample peak on TCD.

The problem here resides in the elemental analyser.

The most common causes are:

- The carousel is not dropping the samples
- The start instruction is not functioning.
- The start stop signal lead has become detached.
- The TCD filament is not switched on.
- The elemental analyser is not in the 'ready' state.

No sample peak at MS, MS OK, sample peak at TCD OK

The problem here is almost certainly the splitter valve being closed.

Sample peak at MS OK, no sample peak on the TCD

The problem here is almost certainly a very large negative offset on the TCD or that the TCD signal lead to the mass spec has become detached.

I have poor chromatography

On both the TCD and the mass spectrometer

This is a pure elemental analyser problem. The most common reasons are

- Poor packing of the reaction tubes
- Poor quality of reaction catalysts particularly the reduction copper.
- GC column temperature too high
- The flow rate through the elemental analyser too high.
- The purge on the carousel is switched off.
- The GC column is contaminated. (Rare)

On the mass spectrometer alone

If there is good chromatographic quality, when inspecting the trace on the TCD, and poor quality on the mass spectrometer, then a component beyond the effluent outlet of the elemental analyser is causing the problem. If the nitrogen peak is good but the CO₂ is bad then suspect a contamination somewhere in the effluent line to the mass spec.

System Controller Error Messages

The errors tabulated below are reported by the system controller as numeric error code, and translated into the text description by the data system software. In the event of an error, the description, along with the command which caused the error, is displayed in the Message Window. If the error code is not recognised by the software, it will be displayed without a text description.

Possible causes are shown below for each type of error. 'Software Errors' are those generated by a bug in the software suite, and should be reported to the Customer Care department.

When reporting an error message to the Customer Care Department, always note down the whole line which appears in the message window, not just the error message itself. It is helpful, if you also note down:

- The operation that was being performed (if any).
- Any suspect behaviour of the software (e.g. Erroneous monitor window data)
- Any message preceding or following the error.

| Code | Description | Possible cause |
|-------------|----------------------------------|---|
| !0300 | invalid command | Software errors Incompatibility between software and firmware versions |
| !0301 | invalid mnemonic | Incorrect mnemonic used in a sequence Old version of firmware, which does not support new prep. system Mimic diagram does not match actual hardware configuration |
| !0302 | invalid argument | Incorrect mnemonic used in a sequence Parameter in sequence or parameter file out of range |
| !0333 | invalid number of parameters | Software error |
| !0400 | invalid beam mask | Software error |
| !0401 | invalid integration time | Integration time in scan window out of range |
| !0405 | bad acquisition command sequence | Software errors |
| !0411 | invalid scan step | Step parameter in scan window out of range |
| !0600 | hardware not present | Incorrect electronics configuration |
| !0601 | invalid hardware type | Errors in configurable mnemonics table |
| !0602 | invalid hardware channel | Errors in configurable mnemonics table |
| !0603 | invalid operation | Software errors |
| !0604 | channel already in use | Software errors |
| !0610 | internal limit reached | Firmware has run out of data space to perform a specific operation |
| !0611 | no more mnemonic space | Configurable mnemonics table too big |
| !0620 | no acquisition hardware | Missing accessory |

Electronics

The following problems may be caused by faults in the electronics systems:

System Crashes

As with any high voltage system, occasional flash-overs (caused by dirty source, high analyser pressure, etc.) can occur. In some circumstances this may cause the microprocessor in the system controller to 'crash'.

Signs that the system controller may have crashed are:

The software error message 'System Controller Not Responding' appears on the PC.

Select OK. If the 'System Controller Not Responding' error appears again it will be necessary to re-boot the system controller by unplugging and reconnecting the mains lead to the unit.

Restart the software.

Problems Controlling the Source/HT Units

If the source cannot be switched on from the software, the most likely cause is a system controller crash as described before. Other possible causes are:

- Turbomolecular pump is not running at full speed.
- The analyser pressure is too high.
- Source connector J1 is not in the correct socket or is not connected.

Magnet Supply Problems (where applicable)

If attempting to change the magnet current results in an 'Invalid Mnemonic' error message or is 'greyed' out in the tune source dialog, the system controller is incorrectly configured.

If the magnet is off despite the programmed current, the possible causes are:

- Cables incorrectly fitted.
- Incorrect voltage setting on power supply
- Blown fuse in power supply.
- Magnet Supply failure.

If the magnet current appears to be full on despite the programmed current, disconnect the power to the magnet controller at its mains inlet to avoid damage to the electromagnet. Check that the cable between the system controller and the magnet supply is intact.

Beam Problems

If it appears impossible to get any beam readings in the monitor window, check that the Head amp. power supply and fibre optic connections are intact.

The head-amp power supply status can be queried using the firmware *read* command using a terminal emulator. See below for details.

Fault Diagnosis Using a Terminal Emulator

If a fault has occurred which could be caused by either software or system electronics, communicating with the electronics directly can help. OS/2 has a terminal emulator which can be used for this. This will usually have been

IsoPrime-EA User Manual

configured during factory testing, however complete instructions are included in the appendix.

- Shut down the data-system software.
 - Open the **OS/2 System** window.
 - Open the **Productivity** window.
 - Start-up the application **PM Terminal**
 - Select the session configured for system controller communications.
- Any characters typed are sent directly to the system controller. A full list of commands is included in the Firmware Manual (included in the appendix), but here are some tips:
- Press the space bar before typing each command to get an echoing prompt.
 - use the read command '**r**' and write command '**w**' to access hardware which is suspect (valves etc.). A full list of mnemonics is included in the firmware manual.
 - The internal commands '**i...**' can be used to get detailed system information. If the Isotopic Analysis factory is contacted with a problem these commands may need to be used.
 - Always leave the cursor at the left-hand margin - not at the prompt - before leaving PMTerminal.

General Notes on Fault Finding

Here are a few very brief guidelines to help you when fault finding.

- **ALWAYS** check every possibility outside the vacuum before opening up the system.
- **ALWAYS** allow plenty of time for the vacuum to come down before assuming that there is a leak.
- **ALLOW** the head amplifier at least an hour to warm up before taking measurements.
- **ALLOW** the magnet at least an hour to warm up before taking measurements.
- **ALWAYS** double check especially when swapping components.
- **ALWAYS** bear in mind that poor results with the VG-ISOCHROM-EA. are only very rarely caused by mass spectrometer or electronics problems. The fault almost invariably, resides within the EA. By far the major causes for poor results, are contamination, leaks, poor combustion, poor chromatography. All of these can be rectified through the maintenance procedures described in this manual.

When the source of the problem has been located the repair must be carried out meticulously to ensure the cure is successful.

Contact details

If, after following the guidance contained within this chapter, you are unable to rectify the fault on your instrument; please contact the Customer Service Department at:

Micromass UK Ltd.
Floats road,
Wythenshawe,
Manchester,
M239LZ,
UK

Phone ++44 (0) 161 718 4575

Fax ++44 (0) 161 718 4660

Or contact your local Micromass representative.

Practical considerations

The aim of this section is to introduce the user to a number of practical aspects associated with sample running. Weighing samples, characterising samples, minimising memory effects between samples are typical aspects which can affect the quality of data produced. It must be heavily emphasised however that the content of this section represents just a small introductory contribution to a much wider sample management discussion effort. The ideas discussed are not intended to be absolute articles of faith, rather they should be used to generate discussion on these and many other subtle aspects of sample analysis which are bound to occur from time to time.

Using the micro balance.

Proper use of a quality micro balance is absolutely essential in order to obtain good reproducible data. A good quality balance is one which can measure to 1 or 2 μg . 1 μg is better but there can be a huge price differential between the two. In either case good performance can only be guaranteed if the balance is placed on a proper solid balance table insulated from vibrational sources. Due to the sensitivity of the Isochrom EA it often happens that sample sizes of around 0.1mg are weighed out. In this case an inherent accuracy of 2 μg can be quite significant to the system when calculating total N or C. For this reason, reference material, should, where possible, be matched with the sample in terms of %N or %C. For example, it makes no sense to attempt to quantitatively measure 1% C using a reference material containing 70% C. Many nitrogen samples, particularly in soils and sediments may contain only 0.1% N so a suitable homogeneously ground lab soil standard containing < 1% N should be used.

IsoPrime-EA User Manual

Balance Equipment

Heavy 6" pointed tweezers

Spatula

EA tin capsule holder

Variety of different size tin capsules

Plastic sample tray 96 sample capacity

Large supply of tissue paper

Procedure

Clean the points of the tweezers

Lift out the sample balance tray and wipe clean and replace

Wipe the spatula clean

Place fresh sheet of tissue on the bench

Place spatula on the paper

Clean the capsule holder and place on the paper

Place a new tin capsule on the balance and tare the weight

Load the capsule with the sample material

Weigh the sample. If sample weight not correct then fiddle about until it is.

Place the loaded capsule on the surface of the sample holder

Using the tweezers close the top of the capsule tightly and fold over.

Squeeze down tightly on fold 1 then fold again

Compress the sample till a compact solid ball is produced

Place in the sample tray.

Repeat process for 3 replicates.

For a new sample repeat the cleaning steps.

Note:

At first sight it may seem reasonable to suppose that smaller tin capsules will contain less carbon blank and in fact this is generally the case. As such common sense says to use the small cups when measuring small samples. However the variation in the blank is inherent to both carbon content and associated delta value of this content so the important thing is to have consistency in both.

Managing memory

Inter sample memory is a problem which is associated entirely with the combustion process of the elemental analyser. The elimination of memory is both difficult and unpredictable. Sometimes the combustion conditions in the oxidation tube are perfect resulting in negligible memory, at other times the memory is pronounced. The following is one explanation as to why this is so.

Consider the surface of the combustion zone, i.e., where the sample lands after the carousel has dropped it into the furnace. If the material making up the surface has poor thermal insulation properties then it is reasonable to assume that as the flash combustion takes place, heat will be conducted away at the contact point between the sample and the surface. It follows that the contact point never reaches the flash combustion temperature of 1700°C and so a small but significant portion of the sample may not combust and is left as a residual to be mixed with the next sample. If however the surface is a very good thermal insulator then heat will not be conducted away resulting in all of the sample, flash combusting at 1700°C. The next question is "what sort of materials are involved"? If the oxidation tube is packed according to the EA manual it will have a top surface consisting of quartz wool. Leave the quartz wool out and it will be a chromium oxide surface. Samples containing little non combustible material will gradually build up a surface associated with the tin capsules. Samples such as soil or sediments on the other hand build up ash deposits. All of these surfaces will have different thermal conductivity characteristics resulting in possibly different memory characteristics. Regardless of the memory characteristics prevailing at the time, it makes sense to construct the autorun in such a manner that any memory effects are minimised.

For example

The samples have been characterised and found to have the following approximate isotopic values

| | |
|---|----------------|
| A | 0.3654 At% N15 |
| B | 1.2345 At% N15 |
| C | 0.8756 At% N15 |
| D | 0.4659 At% N15 |
| E | 1.7439 At% N15 |

It would make sense to construct the batch run in such a way that the jump in enrichment between sample types is reduced to a minimum. As such, the batch file may look like the following.

| Sample | Replicates |
|--------------|------------|
| Blank | 3 |
| Elem Ref n/a | 3 |
| A | 3 |
| D | 3 |
| C | 3 |
| B | 3 |
| E | 3 |
| Elem ref n/a | 3 |

Note that the blank values are measured at the beginning of the batch while the residual memory is at natural abundance level. This is followed by

IsoPrime-EA User Manual

samples increasing in enrichment as the run progresses. Never insert dummy or wash samples in the middle of a run like this as it will serve only to increase the step in enrichment to the next sample. The only time wash samples should be used is to come back down to natural abundance level following the analysis of enriched samples. The elem ref samples at the end of the above run will be valid for quantitative measurements though perhaps not much use as isotopic standards. In the same way, introduction of blanks at the end of this batch will not result in a valid isotopic correction.

Documentation Analysis Report 202/03

Code: 188702

Decision criterias for GC/C/IRMS results

Based on our reference values the following criterias indicate an application of testosterone or testosterone prohormones:

Difference of the $\delta^{13}\text{C}$ [‰]- values between androsterone and pregnanediol > 2.6 or
difference between the $\delta^{13}\text{C}$ [‰]- values of etiocholanolone and pregnanediol > 3.3

GC/C/IRMS - Results

26.02.03

Federation:

Event:

Code-Nr.:

188702

Lab-Nr.:

1013/03 A

Sample receipt:

11.02.03

Results:

The ratio testosterone/epitestosterone is higher than 6
(25.3 ± 0.31 , $n=3$); the GC/C/IRMS results indicate an application
of testosterone or testosterone prohormones

For the sample with the code number 188702 the following $\delta^{13}\text{C}$ [‰]- values were obtained:

testosterone metabolites:

etiocholanolone -30.5 ± 0.2 ($n=5$)

androsterone -29.5 ± 0.3 ($n=5$)

internal reference compounds:

11 β -hydroxy-androsterone -20.46 ; -20.17

pregnanediol -21.1 ± 0.1 ($n=3$)

Conclusions

The $\delta^{13}\text{C}$ [‰]-values of the testosterone metabolites indicate the application of testosterone
or testosterone prohormones.

To: Clients of the UCLA Olympic Laboratory

Regarding: Carbon Isotope Ratio measurements, Update 3

This letter is to update you on our carbon isotope ratio method and to explain the wording we use in our current reports.

DIOL ASSAY

Requests: Currently when you request a CIR analysis we perform the "Diol" assay. The procedure is to request a CIR analysis by fax or email and to provide the sample number. We will check the original data on the sample and determine if the analysis is likely to be successful. If not, we will advise you that we do not believe the analysis will be successful and we may suggest an alternative approach. In order to enhance our understanding of the analysis we also ask that you give us all sample numbers of prior samples from the same athlete that were analyzed at UCLA.

The "Diol" assay determines the carbon isotope ratio (delta value) of two diol metabolites of testosterone which we refer to as M1 and M2, and one metabolite of a testosterone precursor (Pdiol). [See the metabolic map attached.] The assay determines the ratio of $^{13}\text{C}/^{12}\text{C}$ for each of these three steroids. The units are usually called "delta units". In addition to the delta values for these steroids, two other types of measurements are calculated. The first is the ratio of the metabolites to the precursor. Two ratios are calculated: M1/Pdiol and M2/Pdiol. The second is the difference between the metabolites and the Pdiol: M1 Pdiol and M2-Pdiol.

Endogenous reference compound: The Pdiol serves as an endogenous reference compound (ERC). Since it is a metabolite of a precursor (see map) in the testosterone metabolic scheme, its delta value does not change when testosterone is administered. In the typical positive case, the delta values of M1 and M2 are low and the delta value of Pdiol is within the normal range. In negative cases, all three diols have similar delta values. The reporting terminology will be: Positive, Negative, or Indeterminate.

A **POSITIVE** report means that the delta values for both M1 and M2 are at least three standard deviation (SD) units less than the mean (average) of a group of 73 normal males, and the delta value for Pdiol is within 3 SD of the mean of normal males. In addition the two ratios (M1/Pdiol and M2/Pdiol) and the two differences (M1-Pdiol and M2-Pdiol) are more than 3 SD from the range of normal values. These criteria are very conservative because all must be met for the sample to be declared positive.

A **NEGATIVE** report means that all three delta values, the two difference scores, and the two ratios are within the normal range.

An **INDETERMINATE** report means that we were not able to obtain definitive data. The most common reasons for this are insufficient sample volume and low concentrations of the steroids. Since there are several criteria for a positive report, it is also possible that a sample will have one ratio and one difference score that are normal and the other ratio and difference score will be abnormal. Other combinations of results are possible. Based on our current understanding of the theory underlying CIR measurements, we believe that in these mixed cases that we classify as indeterminate, some of the molecules of M1 or M2 are derived from pharmaceutical testosterone (or another exogenous steroid which is metabolized to

testosterone) and some of the molecules are from natural (endogenous) testosterone. This is expected when the body contains a mixture of pharmaceutical and natural testosterone and metabolites. This situation is likely to occur at the later times in the curve that relates delta values to time since drug administration. As our clients gain further understanding of the CIR analysis, you may have other opinions about how we report mixed cases.

SAMPLES FROM OTHER LABORATORIES

Occasionally we are asked to perform a CIR analysis on a sample that was originally processed at another sample. We are not comfortable with this for four reasons: 1) we do not know the details of handling and storage of the sample in the other laboratory, 2) we do not have any control over the chain-of-custody until the sample arrives at UCLA, 3) we do not have screening data (T/E, testosterone concentration, etc.) obtained at UCLA therefore we cannot adequately plan the analysis, and 4) we do not have control samples that were handled in the same way. We do not have any reason to believe that the CIR analysis is affected by storage conditions, time factors, or temperature nevertheless we cannot be absolutely certain that our in-house control data applies to such samples. In the future we will decline to perform the CIR analysis unless there is sufficient sample volume to perform both a steroid analysis and a CIR analysis.

ANDRO & ETIO ASSAY

Under certain circumstances we also offer the Andro & Etio assay. The advantages are that it is simpler to perform, less expensive, and it almost always yields definitive results. The disadvantage is that there is no PdIOL to serve as an ERC, therefore we are not able to calculate ratios or difference scores. Most clients seem to prefer the DIOL assay, however we suspect that in the future the Andro&Etio assay will be developed to the point where the lack of an ERC will not be a disadvantage. At this time we recommend the "diol" assay. Occasionally we will advise you that it is not possible to perform the DIOL assay and that the only CIR option is the Andro & Etio assay.

GENDER

At the present time we do not recommend performing the CIR analysis on samples from females. If you still wish to have the analysis we will determine if it is feasible to proceed based on the existing data from the athlete.

EPITESTOSTERONE

We have been working on a CIR assay for epitestosterone and we have recently presented our findings at a national meeting. There is no peer reviewed publication at this time and it will take about a year to prepare a manuscript and get it published. Nevertheless, at your request we will conduct the epitestosterone analysis on urine samples reported "epitestosterone > 200 ng/ml".

TURN-AROUND-TIME

In an attempt to keep the costs down we are performing the analyses one week per month. Typically this is the fourth week of the month. It takes about a week to complete the analysis, calculate the results, and the issue the report.

In This Book...

This book contains information for using your gas chromatograph (GC) effectively.

1 What Gas Chromatography Is

This chapter describes gas chromatography—its effects and its uses—and the chromatographic hardware.

2 Injecting Samples

This chapter describes the most common ways of getting the sample into the GC.

3 Separating Components

The column separates the sample into components. This chapter tells how this works and how to use it.

4 Detecting Components

This chapter describes three common GC detectors.

5 Interpreting Chromatograms

The final chapter discusses how to identify peaks and how to determine the amounts of each component.

| Instrument control | 15 |

Gas chromatography (GC) is a laboratory technique that separates mixtures into individual components. It is used to identify components and to measure their concentrations.

1 What Gas Chromatography Is

A Separation in Time

Rather than a physical separation (such as distillation and similar techniques), GC creates a time separation.

It does this by passing the vaporized mixture (or a gas) through a tube containing a material that retards some components more than others. This separates the components in time. After detection, the result is a chromatogram (Figure 1), where each peak represents a different component of the original mixture.

The appearance time can be used to identify each component; the peak size (height or area) is a measure of the amount.

Figure 1 A typical chromatogram

The System

A gas chromatographic system consists of:

- A regulated and purified carrier gas source, which moves the sample through the GC
- An inlet, which also acts as a vaporizer for liquid samples
- A column, in which the time separation occurs
- A detector, which responds to the components as they occur by changing its electrical output
- Data interpretation of some sort

This is summarized in Figure 2.

Figure 2 A chromatographic system

The gas source

The carrier gas must be pure. Contaminants may react with the sample or the column, create spurious peaks, load the detector and raise baselines, and so on. A high-purity gas with traps for water, hydrocarbons and oxygen is recommended. See Figure 3.

Figure 3 The gas source.

When a house gas supply, rather than separate tanks, is used, have traps for each GC and place them as close to the back of the instrument as possible.

The inlet

The inlet introduces the vaporized sample into the carrier gas stream. The most common inlets are injection ports and sampling valves.

Injection ports

Handle gas or liquid samples. Often heated to vaporize liquid samples. Liquid or gas syringes are used to insert the sample through a septum into the carrier gas stream. The principle (not a real design) is shown in Figure 4.

Figure 4 Injection port

Sampling valves

The sample is flushed from a loop which is mechanically inserted into the carrier gas stream. Different valves are used for liquids and gases, because sample volumes are usually quite different. The principle (not a real design) is shown in Figure 5.

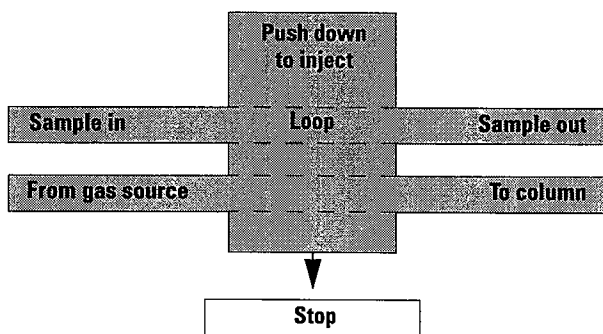

Figure 5 Sampling valve

1 What Gas Chromatography Is

Sample valves are often connected to an inlet, especially the split/splitless inlet in the split mode.

The column

The separation happens here. Because the column type is selected by the user, many different analyses can be performed using the same equipment.

Most separations are highly temperature-dependent, so the column is placed in a well-controlled oven. See Figure 6.

Figure 6 The column and oven

The detector

The gas stream from the column, which contains the separated components, passes through a detector. The output from the detector becomes the chromatogram. See Figure 7.

Figure 7 The detector

Several detector types are available, but all perform the same tasks:

- Produce a stable electrical signal (the baseline) when pure carrier gas (no components) is in the detector.
- Produce a different signal when a component is passing through the detector.

Data reduction

Measurement

The chromatogram leaves the detector as an electrical signal. It can be:

- Recorded on a strip chart recorder
- Processed by a digital integrator
- Processed by a computer-based data system

A strip chart recording must be measured to determine the peak times and sizes. Integrators and data systems perform these measurements directly. They are strongly recommended because of their reproducibility and sensitivity.

Calculation

The list of times and sizes must be converted to component names and amounts. This is done by comparison to times and responses of known samples (calibration samples). This can be done manually, but for speed and accuracy, a data system is best.

Instrument control

Some data system/GC combinations also provide direct control of the GC by the data system computer. This allows the creation of stored methods, which are invoked as needed, and permits a high degree of analysis automation.

1 What Gas Chromatography Is

2 Injecting Samples

| | |
|---------------------------------|----|
| Injection Ports | 18 |
| Packed port | 18 |
| Split/Splitless port | 19 |
| Injection technique | 22 |
| Benefits of automatic injection | 23 |
| Valves | 24 |
| Gas sampling | 24 |
| Liquid sampling | 24 |
| Inlet Temperature | 25 |
| Gas samples | 25 |
| Liquid samples | 25 |

Some samples are already gases (such as room or outside air, heating gas, etc.) and can be injected directly using either a gas syringe or a gas sampling valve.

Most samples are liquids and must be vaporized in order to be analyzed by gas chromatography. This is usually done with a heated injection port in combination with either a liquid syringe or liquid sampling valve.

Injection Ports

The design and choice of injection ports depends on the column diameter and type. The column types, packed and capillary, are described in the next chapter.

Packed columns and wide-bore capillary columns use the packed port; narrow-bore capillary columns use the split/splitless port.

Packed port

The packed port was developed for packed columns. Removable liners adapt it for the specific column diameter, usually either 1/8- or 1/4-inch. A typical design is shown in Figure 8.

When wide-bore capillary columns appeared, liners were created to allow their use with the packed port. These columns have sample capacities similar to packed columns.

Figure 8 Packed injection port

The sample is injected with a syringe inserted through the septum into the carrier gas stream. The heated port vaporizes it (if it is a liquid) and the carrier gas sweeps it into the column.

Split/Splitless port

The split/splitless port, used with capillary columns, has two operating modes.

Split mode

Capillary columns have low sample capacities. Very small sample sizes, usually much less than a microliter, must be used to avoid overloading the column.

It is very difficult to handle such small sample sizes. The split mode provides a way to inject a normal-size sample, vaporize it, and then transfer only part of it to the column for analysis. The rest is vented to waste.

A typical split/splitless port in *split mode* is shown in Figure 9.

Figure 9 Split mode

2 Injecting Samples

The split valve is open and remains that way. The sample is injected into the liner, where it vaporizes. The vaporized sample divides between the column (high flow resistance) and the split vent (adjustable flow resistance).

Splitless mode

This mode is particularly well suited to low concentration samples. It traps the sample at the head of the column while venting residual solvent vapor in the inlet to waste.

Two steps are involved:

1 Sample injection

Close the split valve. The carrier flow divides between the septum purge and the column. The pressure at the head of the column, and therefore the flow through it, is set by the split vent control.

Inject the sample. The solvent, the major component, creates a saturated zone at the head of the column which traps the sample components.

Figure 10 shows the flows at injection in the *splitless* mode.

Figure 10 Splitless mode at injection

2 Inlet purge

After the sample has been trapped on the column, open the split valve. The residual vapor in the inlet, now mostly solvent, is swept out the vent.

The flows are now the same as in the split mode (Figure 9).

Raise the oven temperature to begin moving the components through the column.

This works well for components with boiling points higher than that of the solvent. The solvent peak will be large. The oven temperature profile is used to separate peaks of interest from the solvent.

Splitless mode steps

A successful splitless injection consists of these steps:

- 1 Vaporize the sample and solvent in a heated inlet.
- 2 Use a low column temperature to create a solvent-saturated zone at the head of the column.
- 3 Use this zone to trap and reconstitute the sample at the head of the column.
- 4 After all, or at least most, of the sample has transferred to the column, discard the remaining vapor in the inlet by opening the split vent valve.
- 5 Raise the oven temperature to release the solvent and then the sample from the head of the column.

Starting values

You must experiment to find the optimum parameters. Table 1 contains some suggested starting values:

Table 1 Splitless mode inlet parameters

| Parameter | Suggested starting value |
|----------------------------|-------------------------------------|
| Oven temperature | 10°C below solvent boiling point |
| Oven initial time | ≥ Split vent valve open time |
| Split vent valve open time | Liner volume x 2 / Column flow rate |

Injection technique

Each peak begins as part of a region of vaporized sample surrounded by carrier gas. This width of this region broadens by diffusion while the peaks are in the column. No peak can be narrower than the initial region.

Since it is much easier to separate narrow peaks than broad ones, the width of the initial region must be minimized. The ideal injection is:

- 1 Fill the syringe and adjust the amount.
- 2 Push the needle through the injection port septum as far as it will go (port designers assume that you will do this).
- 3 Press the syringe plunger quickly.
- 4 Immediately withdraw the needle from the port.

The important parameter is speed. Any hesitation leads to increased region width.

A skilled operator can achieve 3 to 4% repeatability in sample size, provided he uses the technique described. Mechanical devices that limit the syringe plunger travel can improve on this.

Avoid techniques in which the sample is trapped between two air bubbles. This requires you to make two estimates and doubles the error in sample size.

Benefits of automatic injection

Automatic injectors provide a solution to the injection problem. They make highly reproducible injections. Because of this, they often permit a simpler calculation of peak amount (external instead of internal standard).

If part of an automatic sampler (equipped with a sample tray and connected to a data system), fully automated analyses become possible.

2 Injecting Samples

Valves

Gas sampling

A gas sampling valve consists of a sample loop and a means of shifting it in and out of the carrier gas stream.

A common form of the mechanism is shown in Figure 11.

Figure 11 Gas sampling valve

Sample size is determined by the sample loop. This is replaceable, so that a single valve can provide a variety of highly reproducible sample injection sizes.

Liquid sampling

The principle is the same as for a gas sampling valve. Because a liquid sample requires a much smaller volume, the “loop” is part of the valve structure and is not replaceable.

To change sample size, you must replace the entire valve.

Inlet Temperature

Gas samples

For gas samples, the inlet does not have to vaporize anything so the inlet does not have to be heated.

However, most chromatographers prefer to heat the inlet to ensure that nothing condenses in it. A temperature of 100°C is often used.

Liquid samples

Liquid samples require a heated inlet. The temperature must be high enough to vaporize the sample but not so high that degradation occurs.

Hot enough Start with the solvent boiling point and examine the peaks. If they are all about the same shape (the sizes will differ), the inlet is probably hot enough. If the later peaks show excess broadening, raise the inlet temperature about 10°C to see if the shapes improve.

Too hot If you have more peaks than components and if they are poorly formed, suspect degradation problems.

Degradation in the inlet creates peaks whose size depends strongly on inlet temperature. To detect this, make a second analysis at a slightly lower temperature. Compare the peak sizes; any significant change could indicate degradation in the inlet.

| Column resolution | 34 |
| Column selectivity | 34 |
| Capillary or Packed? | 35 |
| Column Temperature | 36 |
| Isothermal oven | 36 |
| Programmed oven | 37 |

The separation of a mixture into individual components occurs in the column. Many columns are available to separate mixtures. The choice depends on the nature of the mixture and the kind of information desired. However, all columns function using the same basic mechanism.

How a Column Separates Components

This is a cross-section of a column containing a two-component injected sample (the colored dots). There is no packing or coating; the column is just an empty tube (Figure 12).

Figure 12 An uncoated column

If we look again a few seconds later, the appearance has changed (Figure 13).

Figure 13 A few seconds later

The "sample" has moved to the right because of the carrier gas flow. It has broadened because of the concentration difference between the sample and the pure carrier gas surrounding it.

The components are still mixed.

Now we add a thin coating of a high-boiling substance on the inside surface of the column and repeat the experiment (Figure 14).

Figure 14 A coated column

We can use any coating we wish. In this case, we select one that dissolves the blue-dot component but not the yellow-dot component.

The blue-dot component distributes itself between the coating and the gas. The yellow-dot component stays in the gas phase.

When we examine the column a few seconds later, we find this: Figure 15.

Figure 15 A few seconds later

The yellow-dot component is not attracted to the coating. It moves through the column at the speed of the carrier gas and will emerge first.

The blue-dot component divides its time between the stationary coating and the carrier gas. It travels through the column at a slower speed and will emerge later.

The sample has begun to separate into two peaks.

The basic principles of chromatography

- When a vaporized component is presented with a gas phase and a coating phase, it divides between the two phases according to its relative attraction to the two phases.
- The “attraction” can be solubility, volatility, polarity, specific chemical interaction, or any other property that differs from one component to another.
- If one phase is stationary (the coating) and the other is moving (the carrier gas), the component will travel at a speed less than that of the moving phase. How much less depends on the strength of the attraction.
- If different components have different “attractions”, they will separate in time.

Column Types

Capillary columns

A capillary column is an open tube with the stationary phase coated on its inside surface. There is no packing.

These columns range from about 0.1 to 0.5 mm inside diameter. A typical column length is 30 m. See Figure 16.

Figure 16 A capillary column

Capillary columns produce very narrow peaks. This allows the separation of very complex mixtures. For example, a typical automobile fuel yields between 400 and 500 peaks.

These columns, when made with fused silica tubing, are very inert. Difficult samples such as mercaptans, which tail severely on metal or glass columns, separate to the baseline on such columns.

Capillary columns require smaller samples than packed columns. A special inlet, see "Split/Splitless port" on page 19, allows a convenient-sized sample to be divided before it enters the column.

Packed columns

In a packed column, the stationary phase is coated on a finely-divided inert material to maximize its area and minimize its thickness. The coated material is then packed into a metal, glass, or plastic tube. See Figure 17.

Most metal packed columns are either 1/8- or 1/4-inch outside diameter. Glass columns are generally 1/4-inch outside diameter, but the inside diameter varies to produce the equivalent of the two metal column sizes.

Figure 17 A packed column

Packed columns have high sample capacity, a necessity with older, less sensitive detectors. However, with modern high-sensitivity detectors, this advantage has vanished. Packed columns are still useful for gas samples, but capillary columns offer better resolution for most liquid samples.

Column tubing

Possible tubing materials include:

- Stainless steel—durable, but a relatively reactive surface may cause component loss or peak tailing.
- Glass—fragile, and usually requires treatment to deactivate the surface.
- Fused silica—used only in capillary columns, inert and robust, the preferred material for most uses.

Column Characteristics

The purpose of a column is to produce narrow, well-separated peaks from a multi-component sample. These two purposes are not entirely separate.

Column efficiency

A high-efficiency column produces narrow peaks. See Figure 18.

Figure 18 Column efficiency

Efficiency is determined by the column construction (small tubing diameter and thin stationary phase layer is best) and by the carrier gas flow rate.

See Table 2 for recommended flow rates.

Table 2 Recommended carrier flow rates

| Type | Diameter | Carrier flow rate, mL/min | | |
|-----------|-------------|---------------------------|------------|-------------|
| | | Hydrogen | Helium | Nitrogen |
| Packed | 1/8-inch od | 30 | 30 | 20 |
| Packed | 1/4-inch od | 60 | 60 | 50 |
| Capillary | 0.05 mm id | 0.2 to 0.5 | 0.1 to 0.3 | 0.02 to 0.1 |
| Capillary | 0.1 mm id | 0.3 to 1.0 | 0.2 to 0.5 | 0.05 to 0.2 |
| Capillary | 0.2 mm id | 0.7 to 1.7 | 0.5 to 1.2 | 0.2 to 0.5 |
| Capillary | 0.25 mm id | 1.2 to 2.5 | 0.7 to 1.7 | 0.3 to 0.6 |
| Capillary | 0.32 mm id | 2 to 4 | 1.2 to 2.5 | 0.4 to 1.0 |
| Capillary | 0.53 mm id | 5 to 10 | 3 to 7 | 1.3 to 2.6 |

In each range, the lower value is close to optimum for the carrier gas and column combination. The higher value speeds the analysis without sacrificing very much efficiency.

Even higher flows, above the range given, can be used when separation is great or a shorter column is used. Flows below the range given increase analysis time and may cause an abrupt loss of efficiency.

Gas control

Flow in packed columns is usually controlled using mass flow controllers. Capillary columns, because of the very low flow rates, are usually pressure-controlled.

Some GCs provide electronic pneumatic control (EPC). Such instruments allow setting flows from a keyboard and reading them on a display.

Column resolution

A high-resolution column separates peaks down to the baseline. This is much easier if the peaks are narrow (the column is efficient).

A small change in flow rate can have an appreciable effect on resolution.

Combining the mathematical definitions of efficiency and resolution yields an important result:

Column resolution is proportional to the square root of column length.

This means that increasing column length is *not* an effective way to improve resolution. Doubling the column length doubles the analysis time (and the column cost) but only increases resolution by about 40%.

Column selectivity

This is a less clearly defined property of the stationary phase. Essentially, it is how well a phase differentiates between two compounds. Low selectivity—they elute together. High selectivity—the peaks separate.

Capillary or Packed?

Both have their places. Here are some of the considerations.

- Gas analyses are usually done using packed columns. They have the sample capacity to accommodate the rather large gas samples. Common packings for gas analysis include:
 - Molecular sieve—oxygen, nitrogen, helium, hydrogen, CO₂, CO, methane, etc.
 - Alumina—propane and up.
 - Porapaks—ethane, butane, CO₂, etc.

Some, but not all, of these can be used in capillary columns.

- Capillary columns have higher resolution than packed columns. Even with little selectivity, an adequate separation is often obtained.
- One capillary column can perform a variety of analyses that might require a collection of several packed columns to achieve.
- Useful stationary phases for both capillary and packed columns include:
 - Methyl silicones—non-polar to moderately polar
 - Phenyl methyl silicones (5 to 50% phenyl)—olefins, aromatics, to moderately polar
 - Carbowax (polyglycol)—acids, very polar
- The high resolution of capillary columns often permits trading resolution for time. Since resolution depends on the square root of length, an excellent capillary column can be cut into two very good capillary columns with only a minor loss in resolution. Analysis time is reduced to one-half!

Column Temperature

The stationary phase (coating) in the column has a preferred temperature range.

- The *minimum* temperature is usually a melting point. Below this, you are doing gas/solid chromatography; above it, you are performing gas/liquid chromatography. Results can be quite different.
- The *maximum* temperature is usually related to a boiling or degradation point.

Columns are mounted in a temperature-controlled oven because separations are highly temperature dependent.

The oven temperature can be isothermal or programmed. See Figure 19.

Figure 19 Oven temperature

Isothermal oven

This is the simplest way to run the oven. The oven remains at the same temperature throughout the analysis. It has *advantages*:

- The oven is always ready for a sample analysis.
- There is no recovery time between analyses.

And *disadvantages*:

- Samples with a wide range of component times take a long time to run.
- Because peaks broaden with time, later peaks may be difficult to detect or measure.

Programmed oven

The oven temperature changes, usually upward, during the analysis. The *advantages* are:

- Analysis time is reduced.
- Peak shapes are constant throughout the run, making detection and measurement easier.

The *disadvantages* are:

- Components are subjected to higher temperatures than with an isothermal oven. This could cause degradation of sensitive components.
- The oven must cool to the starting temperature between runs. This cancels part of the time gained.

3 Separating Components

4 Detecting Components

| | |
|----------------------------|----|
| Thermal Conductivity (TCD) | 40 |
| How it works | 40 |
| Flame Ionization (FID) | 42 |
| How it works | 42 |
| Electron Capture (ECD) | 43 |
| How it works | 43 |

The three detectors described in this chapter do most of the GC work. They are augmented by others (see Table 3), mostly element-specific or mass-selective, which are not described in detail.

Table 3 Some other detectors

| Name | Uses |
|------------------------------------|---|
| Nitrogen-Phosphorus Detector (NPD) | Nitrogen- and phosphorus-containing compounds |
| Flame Photometric Detector (FPD) | Sulfur- and phosphorus-containing compounds |
| Atomic Emission Detector (AED) | Tunable for many elements |
| Mass Selective Detector (MSD) | Identify components from mass spectra; when combined with GC, the most powerful identification tool available |

Thermal Conductivity (TCD)

All gases conduct heat, but hydrogen and helium are, by far, the best thermal conductors (see Table 4). When either of these is used as the carrier gas, anything else that may be present causes a decrease in the thermal conductivity of the gas stream.

This change can be measured and used to create a chromatogram.

Table 4 Thermal conductivities of gases relative to hexane

| Gas | Relative thermal conductivity |
|----------------------|-------------------------------|
| Carbon tetrachloride | 0.44 |
| Benzene | 0.88 |
| Hexane | 1.00 |
| Argon | 1.04 |
| Methanol | 1.10 |
| Nitrogen | 1.50 |
| Helium | 8.32 |
| Hydrogen | 10.68 |

Since the TCD operates on thermal conductivity differences, it is clear that hydrogen or helium are the preferred carriers.

How it works

When a voltage is applied to a filament, it heats up. The steady-state temperature depends on the applied voltage, the resistance of the filament, and the rate at which the filament loses heat to its surroundings.

If a filament is immersed in a gas stream, any change in the thermal conductivity of the gas causes a change in filament temperature. This changes the resistance of the filament.

Early TCD designs used four filaments connected as a Wheatstone bridge. The column effluent flowed over two opposite filaments; pure carrier gas (the reference) flowed over the other two. When a component appeared, the bridge became unbalanced.

A modern TCD design is shown in Figure 20.

Figure 20 Thermal conductivity detector

This detector uses a single filament. A rapid switching valve causes it to sample the carrier effluent and a reference gas alternately. If the two gas streams are identical—no component present—the filament resistance does not change when the gases switch.

However, when a component enters the detector, the filament temperature drops when the column flow is switched in and then recovers when the reference gas is switched in. The electronics senses this change and adjusts the power to the filament to keep the temperature constant.

The power demand curve amplitude depends on the thermal conductivity difference between the column flow (when a component is present) and the reference gas.

Flame Ionization (FID)

An air/hydrogen flame creates very few ionized particles. However, if a carbon-containing material enters the flame, ion production increases.

How it works

The carrier gas from the column mixes with hydrogen and is burned in air. The FID uses two electrodes, one of which is often the jet where the flame burns, and a polarizing voltage to collect the ions from the flame.

When a component appears, the collected current rises. After amplification, the current creates the chromatogram.

The FID responds to anything that creates ions in a flame, which is essentially all organic compounds (there are a few exceptions).

A general FID design is shown in Figure 21.

Figure 21 Flame ionization detector

Electron Capture (ECD)

The electron capture detector has found wide use in environmental work because of its very high sensitivity to halogen-containing components, which include most herbicides and pesticides.

How it works

A radioactive isotope, usually ^{63}Ni , in the detector cell emits beta particles. These collide with carrier gas to create showers of low-energy free electrons. Two electrodes and a polarizing voltage collect the electrons as a current.

Some molecules can capture low-energy electrons to form negative ions. When such a molecule enters the cell, some of the electrons are captured and the collected current decreases. After processing, this signal creates the chromatogram.

One form of the ECD is shown in Figure 22.

Figure 22 Electron capture detector

4 Detecting Components

The ECD is quite specific, responding strongly to anything that captures electrons and poorly to everything else. Some relative responses are listed in Table 5.

Table 5 ECD sensitivities to selected compounds

| Compound | Response relative to benzene = 1 |
|----------------------|----------------------------------|
| Benzene | 1 |
| Toluene | 3 |
| Acetone | 8 |
| 2,3-Butanedione | 800,000 |
| n-Butanol | 17 |
| Chlorobenzene | 1,200 |
| Bromobenzene | 7,600 |
| 1-Chlorobutane | 17 |
| 1-Bromobutane | 5,000 |
| 1-Iodobutane | 1,500,000 |
| Chloroform | 1,000,000 |
| Carbon tetrachloride | 6,600,000 |

5 Interpreting Chromatograms

| | |
|---------------------------|----|
| Peak Measurements | 47 |
| Retention time | 47 |
| Peak size | 47 |
| Component Identity | 49 |
| Component Amount | 50 |
| Uncalibrated calculations | 50 |
| Area and height percent | 50 |
| Calibrated calculations | 52 |
| Normalization | 54 |
| External standard | 55 |
| Internal standard | 56 |

5 Interpreting Chromatograms

The chromatograph produces a signal that varies with time. When plotted, it produces the familiar chromatogram (Figure 23).

Figure 23 A typical chromatogram

The chromatogram can be converted into a list of peak times and sizes by either manual or electronic means.

Peak Measurements

Two basic measurements can be made on a peak:

- The time after injection when the peak is detected
- The size of the peak

Retention time

The *appearance time*, measured from injection to detection, is the sum of two parts:

- The *plumbing time*—how long it takes for the carrier gas to pass through the column. It is measured by injecting air or some other non-interacting substance.
- The *retention time*—the additional time caused by the component's interaction with the stationary phase in the column.

For most purposes, the plumbing time is ignored and the retention time is taken as the appearance time.

Peak size

Size can be measured either as peak area or peak height, both measured relative to a constructed baseline.

The baseline under the peak cannot be measured directly. It must be constructed from the baselines on either side of the peak.

This is simple with well-separated peaks. It is much more difficult when peaks are merged, on the trailing edge of a solvent peak, or otherwise less than ideal. For this reason, time spent improving the peak separation is time well spent.

Peak height

This is the simplest measurement, requiring only a ruler. It is the vertical distance from the top of the peak to the baseline.

Peak area

This is the area enclosed by the peak signal and the baseline under it. It is best measured by electronic means.

The two size measurements are shown in Figure 24.

Figure 24 Measuring a peak

Integrators and data systems

Integrators excel at measuring peak areas or heights and peak retention times. They make the conversion of a curve (the chromatogram) into a table (of times and sizes) very simple and reproducible.

Data systems offer the same advantages and considerably more.

- A software integrator is more flexible than that in a hardware integrator.
- Data can be reprocessed using different integration and calculation parameters without re-injecting the sample.
- Systems perform the fundamental calculations described in this chapter, often with more sophisticated features.
- Systems produce user-designed formatted reports.
- Peak calibration becomes a very simple process.
- Both single- and multi-level calibrations are possible.
- Raw and processed data can be archived for later use.
- Systems process data from multiple GCs at the same time.

Component Identity

Because many compounds may elute at the same (or nearly same) retention time, gas chromatography by itself does not usually provide identification of a totally unknown sample.

However, it is a very powerful tool when the problem is more constrained. GC patterns can be compared to identify samples that have a high probability of being the same. For example, crude oil from a tanker can be compared to an oil slick on the ocean to determine if that tanker was responsible for the spill.

GC is quite useful for *eliminating* possibilities. If you know from previous experiment that iso-octane appears at 1.9 minutes, then the unknown peak at 1.5 minutes is definitely *not* iso-octane. But what is it?

Fortunately, you do not have to consider the entire universe of chemical compounds. Sample information limits the list of possibilities. For example, you would not expect to find streptomycin in a paint sample.

When a tentative peak identification has been made, it should be confirmed by repeating the analysis using a column that separates on a different basis. If a component has the right retention time on a boiling point column (methyl silicone) *and* on a polarity column (polyglycol), the identification is probably correct.

GC is especially useful in problems where the expected components are known and quantitation is required. GC will also usually detect the presence of unexpected components (as extra peaks).

Finally, GC can be connected to mass spectrometers or other selective detectors to provide additional data needed for positive identification of unknown components.

Component Amount

Uncalibrated calculations

A detector produces a signal while carrier gas is passing through it. If there is no component at the moment, the signal is the baseline. When a component appears, the signal increases.

The area between the projected baseline and the signal, while the component is passing through, is the peak area. The maximum vertical distance between the signal and the projected baseline is the peak height.

An integrator or data system handles the sometimes very difficult task of drawing the projected baseline, then measures the peak areas and heights. The results are the **Measured Responses (MR)**.

Area and height percent

Each peak is expressed as a percent of the total measured area or height in the run.

The detector is assumed to be equally sensitive to all components. Equation 1 shows the calculation.

$$\text{Amount of peak } n = \frac{[\text{MR of peak } n / \text{Sum of all MRs in the run}] \times 100}{(1)}$$

Advantages

- Fast setup, since no calibration is needed.
- Moderate sample size variation does not affect results.

Disadvantages

- All peaks must be detected.
- Any peaks not detected or not flushed from the column reduce the sum of MRs. This causes overestimation of all measured peaks.

Uncalibrated calculations do not correct for component sensitivity differences. This tends to overestimate the early peaks.

Common uses

- Generating a list of responses and retention times for building a calibration table.
- Analyses where the purpose is fast, reproducible results to be compared with preset limits.
- Useful in process monitoring, product release testing, etc.
- Not useful when absolute accuracy is important.

Calibrated calculations

If Area% and Height% are not adequate, the calibrated calculations use data from standard analyses to create individual peak calibrations.

The simplest calibration is the Response Factor, which is calculated by dividing the known amount of a component by the size of the peak it produces.

Graphically, it is the slope of a plot of component amount versus peak size, as shown in Figure 25.

Figure 25 Response factors

Response Factors can be determined by analyzing a single standard mixture containing all of the components to be calibrated.

However, the Response Factor approach makes two important assumptions:

- The amount/size line passes through the origin.
- The amount/size line is straight.

For a trustworthy calibration, both assumptions must be demonstrated experimentally. If the line is really straight and really does pass through the origin, then the response factor is valid.

In Figure 25, Response Factors can be used for peaks A and B, but not for peak C. The two forms of calibration correction are shown in Equation 2 and Equation 3.

For Peaks A and B:

$$\text{CR of peak} = \text{MR of peak} \times \text{Response Factor of peak} \quad (2)$$

For Peak C:

$$\text{CR of peak} = \text{<Response Curve amount> of MR of peak} \quad (3)$$

Peak C can only be corrected by using the entire calibration curve. This is laborious by hand, but is easily done using a data system.

Normalization

The normalization percent is similar to Area% and Height%, but uses Corrected Responses instead of Measured Responses, as shown in Equation 4.

$$\text{Amount of peak } n = \frac{\text{CR of peak } n}{\text{Sum of all CRs in the run}} \times 100 \quad (4)$$

Advantages

- This calculation corrects for component sensitivity differences, which yields more accurate results for early peaks.
- Moderate sample size variation does not affect results.

Disadvantages

- The method must be calibrated.
- All peaks must be detected. Any peaks not detected or not flushed from the column will reduce the sum of CRs. This causes overestimation of all measured peaks.
- All peaks must be identified and calibrated to achieve the highest accuracy. Unknown (and therefore uncalibrated) peaks reduce the absolute accuracy of the calculation.

Common uses

- Provides very accurate results if there are no high-boilers to worry about.

External standard

The great advantage of external standard is that only the peaks of interest need to be calibrated. The calculation is very simple; see Equation 5.

$$\text{Amount of peak } n = \text{CR of peak } n \quad (5)$$

Advantages

- Only the peaks of interest must be calibrated.
- Only the peaks of interest must be eluted and measured.
- Each calibrated peak is computed independently.

Disadvantages

- Peaks of interest must be calibrated.
- The calculation assumes that instrumental drift is negligible. Known check samples must be run regularly to confirm this.
- Constant sample size is essential, since this is an absolute (rather than relative) calculation. This is very difficult to achieve using manual injection. In practice, a gas or liquid sampling valve or an automatic liquid sampler is a necessity.

Common uses

Gas analyses using a sampling valve. As instrument stability improves, and with the help of automatic injection devices to ensure constant sample size, ESTD is taking over many analyses that formerly required ISTD.

Internal standard

Internal standard provides independent calculation of each calibrated peak. It also corrects for variation in sample size, instrument drift, and other factors.

ISTD is considered the most accurate chromatographic calculation, although ESTD with modern equipment is rapidly improving.

The basic calculation is shown in Equation 6.

$$\text{Amount of peak n} = \left[\frac{\text{CR of peak n}}{\text{CR of ISTD peak}} \right] \times \text{Amount of ISTD peak} \quad (6)$$

The quantity **Amount of ISTD peak** is a known amount of the internal standard compound that is added to each sample before analysis.

This is generally considered to be the most accurate of the calculations.

Advantages

- Only the peaks of interest must be calibrated.
- Only the peaks of interest must be eluted and measured.
- Each calibrated peak is computed independently.
- Minor variation in sample injection size does not affect results.
- Minor instrumental drift does not affect results.

Disadvantages

- Peaks of interest must be calibrated.
- A known amount of an internal standard substance must be added to every sample.

Common uses

Liquid sample analysis where high accuracy is required.

Note

The term internal standard has come to have two slightly different meanings:

- 1 ISTD was originally developed to compensate for differences in manual sample injection size. To do this, the internal standard was added to the ready-to-inject sample after any sample workup (distilling, extracting, etc.) was completed. The main requirements for the internal standard were that it not be present in the original sample and that it produce a well-defined peak that is well resolved from the sample peaks. It did not have to be chemically similar to the sample components.
- 2 In many biochemical and related applications, the internal standard is added to the raw sample before sample workup. In this case, it must be chemically similar to the sample so that it will be affected by the workup steps in much the same way. Now the internal standard is being used to correct for two different things: variation in percent recovery during workup and sample size differences in the injection. This is not possible with a single standard. By precisely controlling the sample workup process and experimentally confirming that percent recovery is highly reproducible, that source of error can be reduced to an acceptable level.

Commonly Practiced Quality Control and Quality Assurance Procedures for Gas Chromatography/Mass Spectrometry Analysis in Forensic Urine Drug-Testing Laboratories

REFERENCE: Goldberger BA, Huestis MA, Wilkins DG: Commonly practiced quality control and quality assurance procedures for gas chromatography/mass spectrometry analysis in forensic urine drug-testing laboratories; *Forensic Sci Rev* 9:59; 1997.

ABSTRACT: Forensic urine drug-testing laboratories operate in a prescribed scientific and administrative manner to ensure accurate test results. All specimens positive by an initial immunoassay test must be confirmed by gas chromatography/mass spectrometry (GC/MS). To provide adequate control and verification of these analytical processes, laboratories must implement appropriate policies and procedures to be used in routine practice. This review describes the following topics regarding GC/MS analyses: method validation, instrument performance, assay calibration, quality control, criteria for designating a positive test result, sample and batch acceptance criteria, and GC/MS data review.

KEYWORDS: Accuracy, calibration, carryover, gas chromatography/mass spectrometry, GC/MS, internal standard, laboratory certification, limit of determination, limit of quantitation, linearity, precision, quality assurance, quality control, sensitivity.

INTRODUCTION

Laboratories accredited by the National Laboratory Certification Program of the United States Substance Abuse and Mental Health Services Administration (SAMHSA, formerly the National Institute on Drug Abuse, NIDA), Department of Health and Human Services (HHS) and the College of American Pathologists (CAP) must perform urine drug testing in a prescribed scientific and administrative manner. Testing of specimens under the CAP and HHS Guidelines requires initial testing by an immunoassay, followed by confirmation of all positive initial test results by gas chromatography/mass spectrometry (GC/MS) [70,72].

To provide adequate control and verification of the analytical process, laboratories must implement appropriate policies and procedures regarding GC/MS analysis. This review is intended to discuss the following topics: method validation, instrument performance, assay calibration, quality control, criteria for designating a positive test result, specimen and batch acceptance criteria, and GC/MS data review. Although this review focuses upon those aspects of quality control and quality assurance pertinent to the regulated drug-testing laboratory, many of the components specified below are directly applicable to any laboratory performing drug testing in biological specimens. Indeed, many of the guidelines reviewed below have been adapted from recommended practices for pharmaceutical methods from the Food and Drug Administration (FDA) and the United States Pharmacopoeia (USP),

as well as recommendations resulting from a 1988 Ad Hoc Committee Report to the American Academy of Forensic Sciences (Toxicology Section) and a 1995 Mass Spectrometry and Good Laboratory Practices Workshop organized by the American Society for Mass Spectrometry [9,69,73,74,80].

I. METHOD VALIDATION

A. Assay Characterization

Method development is a process of documenting or proving that an analytical method is acceptable for its intended purpose. For analytical methods to be implemented in laboratory-based regulatory drug-testing programs, the laboratory must be able to demonstrate that the chosen analytical method has the ability to provide *accurate* and *reliable* data. These data can then be used to identify drug presence in a urine specimen according to pre-established administrative reporting limits (cutoff concentrations). Therefore, it is critical that the laboratory identify the key assay characteristics which it will validate prior to implementation of the method into routine use. Also, the laboratory must clearly define the evaluation criteria for each of the key assay characteristics it has selected as part of its validation. It has been suggested that at a minimum, the key assay characteristics to be established and evaluated should include: the accuracy, precision, linearity, specificity, sensitivity, carryover potential, and ruggedness of the analytical method [29]. Additional

characteristics to be evaluated may include: the stability of the analyte under various analytical and storage conditions, identification and concentration of the internal standard(s) for the method, validation of use of partial (diluted) sample volumes, and estimated recovery of the analyte from the matrix [18].

Specific evaluation criteria for method validation generally accepted by the scientific community for an analytical method can vary depending on the particular technique used (i.e., HPLC, GC/MS, LC/MS), as well as its particular application. Much of the available published information with respect to details of validation protocols, such as the number of batches to be evaluated, the number of replicates, and specific acceptability criteria, is based upon chemical analyses performed on autoanalyzers, or HPLC systems, rather than GC/MS systems [2,18,38,41,78]. Therefore, the application of quality control principles to GC/MS analysis of urine specimens has been based largely upon professional consensus, or "generally accepted laboratory practice" in the drug-testing community. This is in some contrast to a formally and experimentally developed, literature-based approach to implementation of quality control principles to a specific technology. Nevertheless, as individual GC/MS methods for drugs of abuse in urine matrices have been developed and published in the literature, quality control principles have been selected and applied in a variety of ways to assist in the validation of methods and increase confidence in the data that are obtained.

B. Accuracy and Precision of the Analytical Method

Two of the most important assay characteristics to be determined during method validation are accuracy and precision. Together, accuracy and precision determine the error of an analytical measurement. Accuracy and precision are frequently considered together because they are interdependent in assessing the acceptability of a method. The *accuracy* of a method, as used in biopharmaceutical or drug-testing analysis, refers to the closeness of the measured value to the true value for the sample. More specifically, it is a measure of the degree to which a mean obtained from a series of experimental observations agrees with the "true" or "accepted" value of the quantity to be measured. *Precision*, on the other hand, refers to the variability of measurements within a set. It is most often used to demonstrate scatter or dispersion between numeric values in a set of measurements that have been determined under the same analytic parameters.

The accuracy and/or precision of an assay can be determined by comparing test results utilizing laboratory-prepared standards and controls with those obtained with an established reference method and/or by analysis of

standard reference materials, such as those available from the National Institute of Standards and Technology (NIST) and CAP [3,17,22,23,66]. Secondary checks may involve reanalyses of performance test specimens and comparison of laboratory results with target means obtained via alternate methods already known to be accurate. (Reanalysis of performance test samples, however, may be prohibited unless the laboratory has obtained prior approval from the submitting agency.)

Accuracy is generally expressed as the percentage difference from the actual value (%DFA) as shown below:

$$\%DFA = [(\text{Mean} - \text{Spiked}) / \text{Spiked}] \times 100$$

An alternate way to determine accuracy is to determine whether the measured mean value is statistically different from the actual value using a *t*-test at 95% confidence [37]. The assessment of accuracy must be carried out on mean values which have been calculated from replicate measurements of reference materials containing known concentration of analyte. At a minimum, triplicate measurements are necessary to establish a single mean value and standard deviation (SD) for any single target concentration. During validation of the assay, it is generally accepted practice to assess accuracy at two to three different concentrations of analyte.

The specific concentrations used for the accuracy evaluation are selected to test accuracy across the range of the standard curve (calibration curve) of the assay. It has recently been recommended that accuracy be assessed using a minimum of 9 determinations over a minimum of three concentrations (e.g., 3 concentrations with 3 replicates each) [65,68]. Other authors have recommended a minimum of 36 determinations over a minimum of 6 concentrations (e.g., 6 concentrations with 6 replicates each) [78].

As stated earlier, the acceptability criteria for accuracy and precision for an assay should be preselected by the laboratory. Generally, accuracy acceptability ranges in forensic urine drug-testing laboratories do not exceed 20% (by convention) of the target concentration. Many laboratories routinely use lower ranges, such as 10%. It should be noted that the acceptable accuracy range selected for initial method validation may differ from that selected for routine use (batch acceptance criteria). For example, a laboratory may require that accuracy be within 10% of the known concentration during method validation, and then choose to increase the acceptable range to 20% for routine daily analysis to accommodate both random and systematic error [38].

Precision of an analytical method is usually assessed in two ways: analysis of multiple measurements during a single analytical run (within-run precision) and analysis

of single, or mean, measurements over many runs (between-run precision). Precision is expressed as the percentage relative standard deviation (%RSD), also referred to as the coefficient of variation (CV), as shown below:

$$\%RSD = [\text{Standard deviation} / \text{Mean}] \times 100$$

Within-run precision can be considered a measure of the precision of an analytical method under optimal conditions. The between-run precision, however, is likely to be a better representation of the precision one might observe during routine performance of the assay because these data are generally subjected to a greater number of sources of variability. The lower the calculated CV, the greater the precision of the assay. Precision of an assay at concentrations below, at, and above the assay cutoff concentration can be determined by repeated analyses of quality control samples on a within- and between-batch basis. One approach to assessing between-run precision of the method is to perform triplicate measurements on three separate concentrations of analyte, across three separate analytical batches. Subsequently, the laboratory evaluates the acceptability of the precision of the method using a criterion selected *a priori*. Generally, within-run and between-run coefficient of variation values of <15% are considered acceptable [2,18,29,33,78]. However, because greater variability is to be expected as analyte concentrations approach the limit of detection (LOD) of the analytical method, the laboratory might choose to increase the acceptability criterion to 20% at its lowest measured concentrations [37].

Finally, an additional technique for evaluation of between-run precision data is to apply a one-way analysis of variance (ANOVA) of the data to ensure that results do not significantly differ between analyses [37,42].

C. Linearity of the Analytical Method

The full range of linearity of a method should be established during initial assay characterization and periodically thereafter with specimens containing drug analytes over a wide range of concentrations. Further, the practical range of linearity, referred to here as the daily linear range, should be documented with every batch based upon data obtained with standards and/or controls [29,65]. Acceptance criteria for evaluating linearity data must include review of chromatographic appearance, retention time, and ion ratio or full-scan spectra matching criteria, for example. Although some analytical procedures may require nonlinear calibration, it is conventional for forensic urine drug-testing laboratories to utilize a linear model and univariate regression for GC/MS analysis. In this model, the independent variable is concentration (X) and

the dependent variable is response (Y), i.e., the value determined by the value of the independent variable. Recommendations for linearity studies are noted below; issues with respect to acceptability of daily assay calibration (range) are considered in a subsequent section of this paper.

In practice, linearity should be established via visual evaluation of a plot of signals (response) as a function of analyte concentration. If a linear relationship appears probable by inspection of such a plot, test results should be evaluated by an appropriate statistical method, such as the method of least squares regression [6,7,29]. Other statistical approaches must be clearly justified by the laboratory. Data from the regression line, such as the correlation coefficient (r), coefficient of determination (R^2), slope, and residual sum of squares, can also provide useful mathematical estimates of the degree of linearity obtained with the analytical method. In addition, since it is not uncommon to expect an increase in variance as a function of concentration, it may be more appropriate to perform a weighted (rather than unweighted) regression analysis to improve accuracy at the lowest concentrations studied [8].

During initial method validation, the laboratory typically analyzes a series of standards (calibrators) that have been prepared at known concentrations of analyte. Data are plotted and analyzed as just described to determine the upper and lower boundaries of linearity. A frequently used criterion for determining the upper and lower boundary limits in the pharmaceutical industry is the point at which the slope of the line deviates from the overall slope by not more than 5% [20]. However, this recommendation is not originally based upon GC/MS analysis. An alternative is to "reverse calculate" the individual concentrations of each standard using the generated regression line and determine whether each is in compliance with the acceptance criteria established for evaluation of quality control samples (e.g., such as $\pm 20\%$ of the target value). Outliers may be identified as those concentrations of analyte at either extreme (high or low) which are outside the 20% criterion. Acceptable linearity, therefore, is demonstrated when the correlation coefficient exceeds a defined value, such as 0.990, and quantitative concentration of each point falls within $\pm 20\%$ of the target value. The discussion regarding evaluation criteria for linearity can be found in Section III.

The laboratory uses this information to establish the range, or concentration interval, which will routinely be used for analysis of samples. Validating the method over a wider range than that used in daily practice provides increased confidence that the routine standard concentrations are well removed from nonlinear response concentrations. If the laboratory elects to perform the linearity

assessment on more than one occasion, a statistical test of linearity can be performed for each standard curve separately using a weighted ANOVA [8,42].

D. Specificity of the Analytical Method — Interference Studies

Specificity refers to the ability of the analytical method to accurately measure an analyte response in the presence of all potential sample components. All methods should at a minimum be investigated for potential interference by endogenous matrix components, as well as common compounds that are structurally similar to the analyte of interest. A complete review of interference studies published regarding forensic urine drug-testing analytes is beyond the scope of this paper; however, some examples are provided below to illustrate general principles.

The potential interference of endogenous urine components with the assay is most frequently assessed by evaluation of urine specimens from several sources (donors) that are known to be drug-free for the analyte of interest. Assessment of interference from structurally related compounds can be determined by fortification of urine with high concentrations (e.g., 1 mg/mL) of potentially interfering analytes and cutoff concentrations of target analytes, or with concentrations of analytes that are expected under therapeutic conditions. For example, possible interference with the measurement of amphetamine and methamphetamine may occur due to the presence of sympathomimetic amines such as ephedrine, pseudoephedrine, phenylpropanolamine, and phentermine [32]. Further, interference with the measurement of morphine and codeine due to the presence of opiate metabolites and synthetic 6-keto-opioids such as dihydrocodeine, hydro-morphone, hydrocodone, oxycodone, and oxycodone has also been described [25].

The determination of potential interferents that are *not* structurally related to the analyte of interest is more difficult to establish. However, the urine drug-testing laboratory may consider evaluating the potential interference of common over-the-counter products, as well as frequently encountered compounds which produce fragment ions also produced by the analyte of interest. In addition, the laboratory may refer to literature reports for interferences experienced by other investigators and assess their method with the potential interfering substances [34,59,67,79]. Although a laboratory cannot be expected to anticipate all potential interferents with its analytical method, it should make its best effort to characterize them whenever feasible.

The problem of interfering substances may be addressed by employing more selective extraction methods,

chromatographic separations, or detection methods. For example, to eliminate potential-false positive amphetamine/methamphetamine results due to the presence of other sympathomimetic amines, aliquots of specimens can be treated with a solution of 0.035 M sodium periodate at room temperature, then subjected to extraction. In the presence of periodate, α -hydroxyamines undergo oxidative cleavage removing the potential interferant [24]. Recent evidence indicates that periodate oxidation should be conducted at pH 7 or lower to prevent possible formation of low levels of amphetamine from extremely high levels of methamphetamine that may be present in the specimen [57]. In addition, lowering the injection port temperature of the gas chromatograph, coupled with other preventative measures, eliminates artifactual production of methamphetamine in the presence of high concentrations of ephedrine and/or pseudoephedrine [24,57,67]. It should be noted that some reported interferences may be method-specific and thus will need to be evaluated by the laboratory on an individual basis, as appropriate.

E. Sensitivity of the Analytical Method — Relationship to Limit of Detection and Quantitation

An analytical method is determined to be *sensitive* if small changes in concentration cause large changes in analytical response. It is directly related to, and frequently defined as, the slope of the standard curve [38]. However, this definition does not account for the variability of a measurement. The limit of detection (LOD) and limit of quantitation (LOQ) are terms which are used to express the ability of the assay to detect small concentrations of analyte, as well as attempting to account for variability of measurement.

The *limit of detection* of a method is the lowest analyte concentration that produces a response detectable above the noise level of the system. The *limit of quantitation* is the lowest concentration of analyte that can be accurately and precisely measured. The LOD and LOQ of a method are dependent upon several factors, such as the electron multiplier voltage, the volume of specimen analyzed, the detector threshold, the type and condition of the chromatographic column, the concentration of analyte, the amount and type of internal standard, the extraction efficiency, and the individual instrument [54]. A significant change or modification to any of these factors will require reassessment of the LOD and LOQ for the method.

There are several approaches for establishing the LOD and the LOQ of an analytical method [1,44,48,65]; at least two of these are routinely used in forensic urine drug-testing laboratories. Recent publications have defined issues of concern regarding LOD and LOQ determi-

nation methods, and have described and compared the two most commonly used methods [1,44].

The first approach to establishing the LOD and LOQ of an assay is based on the measurement of the magnitude of analytical background noise. It is performed by analyzing an appropriate number of blank (drug-free) samples and calculating the standard deviation of these responses. In practice, determining LOD using this approach involves the analysis of negative urine specimens (obtained from at least ten different donors) over time. In this paradigm, the LOD is calculated as the mean of the detected amount or signal intensity plus three standard deviations ($\bar{X} + 3 \text{ SD}$) [48], where 3 is a factor for a 99.9% level of confidence. Similarly, LOQ is calculated as the mean of the detected amount or signal intensity plus ten standard deviations ($\bar{X} + 10 \text{ SD}$). An obvious limitation of this approach is that while this may be an adequate measure of the theoretical LOD of a method, actual concentrations of analyte in biological samples measured at this calculated LOD would be indistinguishable from zero measurements by a large probability [38].

The second commonly employed approach for the determination of LOD and LOQ is based on a signal-to-noise comparison [65]. Determination of the signal-to-noise ratio is performed by comparing measured signals from samples with low concentrations of analyte with those of blank samples and establishing the minimum concentration at which the analyte can be reliably detected. In this context, a minimum of a signal-to-noise ratio of 3:1 or greater is generally agreed to be acceptable for LOD assessment; a signal-to-noise ratio of 10:1 or greater is generally agreed to be acceptable for LOQ assessment. In practice, this approach involves analysis of a series of samples containing low concentrations of analyte.

For GC/MS analysis in urine drug-testing laboratories, SAMHSA defines the lowest analyte concentration that meets signal-to-noise, chromatographic, retention time, and ion ratio or full-scan matching criteria, as the LOD. The lowest concentration, that meets all of the above criteria and quantitates within $\pm 20\%$ of the target concentration and measures within a specified coefficient of variation, is designated as the LOQ.

The first two approaches described above are routinely utilized in laboratories performing regulated urine drug testing, although the second approach is preferred over the first approach since it is based upon measurement of an actual analyte response, rather than the absence of a response. A third approach to determination of LOD and LOQ values is based on the standard deviation of the analyte response and the slope of the standard curve. In this case, the LOD is expressed as 3.3 times the standard

deviation of the response divided by the slope (S) of the calibration curve ($3.3 \times \text{SD}/S$). The LOQ is expressed as 10 times the standard deviation of the response divided by the slope of the calibration curve ($10 \times \text{SD}/S$). The slope is estimated from the standard curve of the analyte, and the standard deviation is estimated by analysis of blank specimens, as described for the first approach. Alternatively, the residual standard deviation of a regression line or the standard deviation of y-intercepts of regression lines may be used as the standard deviation. It has been recommended that if the detection limit of an assay has been estimated by calculation or extrapolation, such as with the first or third approach described above, this estimate should be subsequently evaluated and validated by the independent analysis of a suitable number of samples known to be prepared near or at the detection limit [65].

The LOD is an important assay parameter due to the use of this value to evaluate retest results. The LOQ is important for defining the minimum accurate quantitative value of the assay. For example, dilutions that produce results less than cutoff but equal to or greater than the LOQ may be utilized with the appropriate dilution factor to calculate test results if the LOQ control included in the batch is found to be acceptable. Dilutions that produce results below the LOQ are not acceptable; specimens must be reassayed at a lower dilution. At least one publication [18] recommends that the assessment of the LOQ be obtained using LOQ samples that are prepared *independently* from that included in the standard curve because the LOQ standard that is included in the standard curve influences the regression equation (and thus is no longer an independent measure). Also, since the LOD and LOQ values are influenced by a variety of factors, such as the individual instrument or detector, it may be advisable for the laboratory to assess these parameters on each instrument used for a particular assay, although a general consensus on this issue has not yet been reached.

Interestingly, there are no requirements and few specific recommendations regarding the number of analyses or analytical runs to be evaluated for LOD and LOQ determination. Suggested numbers of replicates of any single blank or standard range from 10 to greater than 20 [19,55,56]. However, from a statistical standpoint it may be advisable to perform these replicate measurements of each blank or standard, in three separate batches, followed by *t*-tests or one-way ANOVA to determine if the calculated LOD and LOQ values differ significantly over time. A two-way ANOVA may be used to determine if a bias is present between instruments.

Finally, in an effort to reduce interlaboratory LOD and LOQ variation, and to introduce a sample that assesses minimum performance in each confirmation batch,

SAMHSA suggested that the LOQ achieved by the laboratory must be a value equal to or less than 40% of the assay cutoff concentration [71]. To ensure acceptable performance, it is desirable to challenge the limit of sensitivity in each batch by including a quality control sample at this concentration to monitor day-to-day instrument and assay variance.

F. Carryover

The term "carryover" is used to refer to the contamination of a sample by a sample analyzed immediately prior to it [35,63]. In the urine drug-testing laboratory, the term "carryover limit" is used to delineate the concentration of analyte in a sample above which contamination may reasonably be expected to occur. There is at least one common approach to performing such studies that involves the analysis of standards prepared at increasingly higher concentrations of analyte, preferably reflecting the highest concentrations which a laboratory typically encounters during routine analysis of samples. Each standard should be injected separately, followed by injection of a blank or solvent to determine if a signal (response) characteristic of the analyte is present in the sample above a pre-established limit (typically the LOD of the analytical protocol). Once the concentration at which carryover occurs is determined, the laboratory establishes its carryover limit at the next lowest concentration which *does not* have evidence of carryover in the blank or solvent. More precisely, upon completion of carryover studies, a laboratory should define the range of analyte concentrations at which carryover does not occur.

The laboratory should also ensure that the quantitative value for the carryover limit established in the carryover study falls within the linearity of the assay to ensure that the quantitative value is accurate. It is also advisable to evaluate carryover of an assay on each instrument system, including autosamplers, on which the method is to be performed, although there is no general consensus on this issue. This is to ensure that the established carryover limit is properly applied to data obtained on each system routinely used in the laboratory.

To minimize potential carryover, one or more of the following approaches can be utilized:

1. Use extensive solvent wash procedures between injections.
2. Inject solvent between all subject specimens.
3. Dilute the specimen prior to extraction.
4. Periodically determine or reassess the minimum carryover concentration.
5. Assay specimen extracts in ascending concentration order (according to initial immunoassay test results).
6. Reinject all highly concentrated specimens followed

- by solvent blanks or negative quality control samples.
7. Assay a carryover standard followed by a solvent blank or negative quality control sample with each batch to assess carryover at the time of testing.
8. Frequently monitor the level of solvent available in the rinse vial for the autosampler to ensure that a sufficient quantity is available for the entire run.

It is important that criteria be established for evaluating the acceptability of solvent blanks or negative quality control samples that have been inserted to assess possible carryover [80]. If carryover is suspected, a potentially contaminated specimen should be re-extracted, rather than reinjected, because the extract vial may have already been contaminated.

G. Other Factors

Other factors, such as selection of a derivatizing reagent, selection of the internal standard(s) for the assay, selection of ions to monitor for selected-ion monitoring or full-scan analysis, stability of the analyte under various storage conditions, estimation of recovery of the analyte from the matrix, and evaluation of the ruggedness of the analytical protocol, should also be determined during the validation of an analytical method [10,18,29,37,38,78].

Selection of a *suitable derivative* is a critical component of assay development and method validation. There are at least three major reasons for using a derivatized compound. First, the analyte can often be made sufficiently volatile to allow its introduction to the mass spectrometer by gas chromatography, permitting optimal separation of the analyte from possible interfering substances. This, in turn, usually increases the specificity, precision, and sensitivity of the assay. Second, the stability of the analyte during storage, isolation, and thermal volatilization can be enhanced via formation of the derivatized product. Third, the increase in molecular mass resulting from derivatization may be beneficial, providing ions which, by virtue of their higher mass, are more specific for the analyte [28,43]. In cases where two or more derivatives are possible, each should be tested to assess its stability, chromatographic peak shape, and mass spectral properties in the biological matrix. The ideal derivatization procedure should be convenient and rapid to perform, form a consistent and stable product in high yield, require small volumes, be selective for the analyte of interest, be safe to handle, and should not form by-products that interfere with the analysis [4,5,39,40,52].

The selection of a *suitable internal standard* is highly linked to the appropriate selection of a derivative for the assay (if necessary), as well the particular ions to be monitored for analyte identification and quantitation. An

ideal internal standard behaves identically to the analyte throughout the extraction, chromatographic separation, and ionization processes. Stable isotope internal standards appear closest to meeting these criteria. The isotope label exerts only a slight effect on the physical properties, yet the higher mass of the isotope-labeled ions of the internal standard permits them to be readily distinguished from analyte ions by the mass spectrometer [16,26,50,58]. Deuterium-labeled analogs [^2H] are most frequently used as internal standards in urine drug-testing laboratories; other isotope-labeled analogs, such as ^{13}C or ^{15}N , are not commonly used.

Several factors are important to consider when selecting the deuterium-labeled internal standard to be used in an assay. The isotope should not undergo exchange under any of the conditions under which it will be used, such as the extraction, derivatization, or chromatographic separation procedures, as well as at the mass spectrometer's ion source [26]. In addition, the isotope must be stable under routine storage conditions, so that exchange of deuterium and hydrogen does not occur [50]. The isotopic variant selected should have a molecular weight three or more mass units greater than the unlabeled compound because the naturally occurring heavy isotope content of organic compounds in general produces ions of significant intensity at one or two mass units above each carbon-containing compound in the analyte's mass spectrum [26,45-47]. It is therefore critical that the isotopic variant is of high purity (>99%) to prevent interference with the analyte of interest during the analysis. Also, the labeling should be in such a manner that the isotopic atoms are located in proper molecular structure so that, after the fragmentation or ionization process, a sufficient number of high-mass ions that retain the label are present in significant intensities and will not interfere with the intensity measurement of the corresponding ions derived from the analyte [46].

The laboratory must carefully evaluate the concentration of internal standard used in its assay to ensure that there is no contribution to analyte signal itself. In effect, the substance ratio of internal standard material to analyte should be selected to give the least imprecision of quantitative analysis and to afford equal ion signal responses during mass spectrometric analysis of the analyte. Under certain conditions, improved sensitivity may be observed by the addition of a large excess of isotopically labeled analogue to reduce adsorptive losses ("carrier effect"). However, this approach is not generally preferred in urine drug-testing laboratories, where a specific administrative cutoff value must be applied. When excess deuterated internal standard is used, analytical precision usually suffers [43], which would not be desirable when a specific quantitative cutoff is needed. Therefore, it is recom-

mended that the laboratory eliminate or minimize adsorptive losses, rather than add excessive amount of internal standard.

The choice of *ion or ions to be monitored* for GC/MS assays has an important influence on analytical specificity. Generally, ions of high, even mass-to-charge ratios have fewer possible origins and are therefore more likely to be characteristic of a particular analyte. The laboratory initially performs a preliminary ion selection based on full-scan mass spectrometric analysis. Ions of high mass-to-charge ratios and good intensity are the first choice for use in routine assays. It is recommended that laboratories using selected-ion monitoring utilize at least three characteristic ions for the analyte of interest, and a minimum of two characteristic ions for the internal standard [72].

Laboratories using full-scan GC/MS must identify those ions with sufficient signal intensity and high-mass to use for qualitative identification of the compound ("matching criteria"). The laboratory should be able to demonstrate that the full-scan spectra it achieves, and plans to use on a routine basis, is stable and reliable over time. Further consideration of these requirements is discussed in Section V.

While most forensic urine drug-testing laboratories are using electron impact ionization (EI) for GC/MS assays, chemical ionization (CI) MS may also be utilized as the mode of detection to improve assay sensitivity and specificity. Chemical ionization MS typically produces an intense molecular ion and only a few fragment ions; therefore, one or two analyte ions may be monitored. A further discussion of these two methods of ionization are beyond the scope of this paper; however, the use of CI is acceptable only if the selectivity, accuracy, and precision of the CI process and method have been fully evaluated [26,81].

Another important parameter to assess during the method validation phase is that of *stability of the analyte*. This includes stability of stock solutions of analyte as well as stability of the analyte in biological matrix. Stability studies will typically be performed to assess stability under different temperatures (storage conditions) and different lengths of time (in-process stability and long-term stability). Stability of the analyte can be assessed at room temperature, refrigerated, and frozen storage conditions. The length of time under each storage condition to be evaluated can range from days to weeks. It is recommended that the laboratory at least establish analyte stability under its own anticipated storage and processing conditions. Although there are many different approaches to the performance of stability studies, a common approach is to use quality control materials prepared at known concentrations to assess stability [18].

Recovery of the analyte from a biological matrix must be determined to ensure that it is adequate and consistent. It is recommended that recovery studies be performed across the range of the standard curve, preferably at the lowest, mid-range, and highest concentrations encompassed by the curve [18,61,78]. Typically, a set of samples of known concentrations is prepared in triplicate at three different concentrations, internal standard is added, and the sample then extracted, derivatized, and analyzed by the GC/MS procedure. A second set of samples is also concurrently analyzed; however, the internal standard is not added until just prior to derivatization. Recovery is then calculated by comparing the calculated concentrations of the two sets of samples and expressing total recovery of the method as a percent. Intermediate points in the extraction process may also be evaluated.

The *ruggedness and reliability of the assay* should be established. Critical assay steps need to be identified, including assessing the importance of pH, solvent mixtures, derivatizing reagents, and temperature and incubation times utilized during the hydrolysis and derivatization processes. In addition, the level of expertise required to perform the analysis needs to be assessed. It must be determined whether the assay can be stopped and restarted, and how long the derivatized analytes are stable. A system for monitoring assay performance variables such as the number of rejected batches, calibration curve parameters (including slope, y-intercept, and correlation coefficient), and quality control results must be established [42,65,78].

II. INSTRUMENT PERFORMANCE

A. Instrument Checks

In addition to developing validated assays for the purpose of identifying and quantitating drugs in urine, it is an essential quality assurance component that the laboratory monitor and document that all analytical instruments involved in the analysis are maintained and operated properly. The laboratory must establish that the instrument used for a particular analysis is operating adequately and within expected performance specifications. Prior to the start of an assay, the condition of the GC/MS system must be evaluated. The GC/MS operator should check the injection port, detector and oven temperatures, and carrier gas pressure, and perform routine maintenance, as needed, such as clipping of the GC column and replacement of the injector septum and liner. In addition, on a periodic basis, or when a new column is installed, the carrier gas flow rate should also be measured.

Routine maintenance should be performed at least as often as recommended by the manufacturer. Additional maintenance and instrument check schedules should be developed by the laboratory according to its workload and type of assay performed. For example, the laboratory may choose to routinely replenish or replace vacuum pump oil on a quarterly basis. Or, the laboratory may choose to replace injection port liners daily. Other types of maintenance procedures include replacement of filaments, cleaning of the ion source, and replacement of electron multiplier or ion gauge. The specific schedule developed by the laboratory will be dependent upon the type of GC/MS instrument used (e.g., traditional quadrupole, ion-trap), as well as the nature of the extracts analyzed on a particular system. The GC/MS laboratory must maintain records of all routine and nonroutine maintenance performed prior to analysis of specimens, as well as written standard operating procedures for the performance of these tasks [9,26,31,53,80]. Record keeping for maintenance procedures is vitally important to demonstrate the validity of the analysis [31].

B. Instrument Performance Evaluation and Tuning

On a daily basis, it is a good practice to check the pressure in the ion source and in the analyzer, as well as the GC column head pressure to assure that no major system leaks have occurred. For quadrupole operation, a pressure of 10^{-4} torr or better is required so that significant interaction between the ion beam and residual gas molecules does not occur (which causes scattering of the ion beam and loss of sensitivity). For GC/MS, an even lower pressure of 10^{-5} torr is necessary to reduce residual gas in order to prevent significant distortion of mass spectra and reduce background interference. Chemical ionization MS typically requires higher source pressure than EI MS.

Following this initial pressure check, the laboratory should verify that there are no significant air/water leaks in the system by monitoring the intensity of the following ions: m/z 28 (N_2^+), 32 (O_2^+), 40 (Ar^+), and 44 (CO_2^+). If these peaks are abnormally large, an air leak may be indicated. In addition, evaluation of water vapor in the system can be checked by monitoring m/z 18 (H_2O^+) and 19 (H_3O^+). Appropriate instrument maintenance must be conducted before analysis is permitted to proceed.

A GC/MS "tuning procedure" ensures that appropriate mass-to-charge assignments and abundances of specific ions have been established, as well as indicating the need for instrument preventative maintenance. In order to verify proper calibration and operation of the mass spectrometer, the instrument must be tuned daily with an appropriate tuning compound (e.g., perfluorotributyl-

amine, PFTBA) for proper unit resolution and mass assignment. "Resolution" refers to baseline separation between consecutive integral mass peaks. In mass spectrometry, resolution and sensitivity are inversely related. Tuning should be performed at the operating temperature of the ion source.

Autotune procedures typically utilize a preselected set of criteria across a range of mass-to-charge ratios (e.g., m/z 69 to 502 for PFTBA) to optimize source and quadrupole potentials. Alternatively, manual tunes can be used to increase sensitivity over a narrower mass range. Autotune procedures, or optimization of tuning parameters across a wide m/z range using a manual tune, are most useful for analysis of unknown specimens. Narrow-range manual tunes can be useful for some low-level target compound analyses. In this case, either of the abundant ions at m/z 219 or 414 can be used to optimize source potentials, depending on which is closest to the analyte and internal standard ions that will be monitored. Manual tuning is acceptable as long as the MS operator is appropriately trained, the tune procedure is fully documented, and the laboratory's standard operating procedure (SOP) manual describes the task clearly and accurately. It is most common, however, for urine drug-testing laboratories to perform an autotune across the entire mass range (e.g., m/z 69 to 502) at approximately 70 eV [9,26,31,43].

All tune reports should be reviewed thoroughly by the operator before testing is initiated to support compliance with manufacturer and laboratory specifications. Acceptable limits should be established for the ion focus, ion appearance and peak width, abundance of selected ions, isotope ratios, and mass slope, as appropriate for the GC/MS instrument. Critical tune values should be monitored on a regular basis, and all tune reports, including unacceptable ones, should be archived as important supporting forensic documents. Autotune, or manual tune, information should be available during review of the batch to ensure that instruments were performing as expected prior to analysis of specimens. These records may be filed with the pertinent batch, or filed in a manner to permit easy retrieval [72].

C. Chromatographic Performance

The chromatographic performance of an assay should also be assessed before the analysis of specimens. This is achieved readily by the injection of an unextracted performance standard including analyte(s) and internal standard(s). Use of an unextracted standard removes sources of variation due to the extraction procedure and matrix interferences. In addition to permitting evaluation of the quality of the chromatographic system, the analysis

of an unextracted standard serves to verify that the analyte(s) of interest elute at the expected retention time, that all MS acquisition windows are appropriately set, and that no unexpected adsorptive system losses have occurred. Evaluation criteria in the SOP manual should include a thorough description of peak shape, resolution, and signal abundance requirements.

One approach to evaluation of acceptable chromatography for a single specimen and/or an entire batch of specimens may be defined and assessed by the following criteria:

1. The analyte of interest is present at the correct retention time.
2. The peak of interest obtained from the total ion chromatogram and each individual ion chromatogram is inspected visually for geometric symmetry. A gaussian peak shape (see Figure 1) is required and shall have no greater than 50% tailing using the following procedure:
 - a. Draw a vertical line from the apex through the center of the peak to the baseline.
 - b. Draw a line parallel to the baseline at 10% of the peak height.
 - c. Measure the distance "a" from the leading edge to the centerline.
 - d. Measure the distance "b" from the centerline to the trailing edge.
 - e. Calculate the ratio of distance "a" and distance "b".
 - f. If the ratio is greater than 2 or less than 0.5, performance is unacceptable.
3. The peak of interest is inspected visually for the presence of unresolved peaks. The maximum allowable valley between two adjacent peaks must not exceed 10% of the analyte peak height.
4. Abundance or signal-to-noise levels of the internal standard ions must meet established minimum criteria.

Failure to meet any of these criteria may provide cause for reinjection or reextraction of a specimen. A complete review of methods for evaluation of chromatographic performance is beyond the scope of this paper; however, acceptable alternative criteria for evaluation of chromatographic acceptability can be found in many textbooks and other reference materials [30,36,49,51,60, 63]. Some instrument software designers are also developing programs for automated evaluation of chromatography.

In addition to daily chromatographic checks prior to batch analysis, performance of the chromatographic column should be evaluated upon installation and periodically thereafter. This can be accomplished by the analysis of a variety of "test mixtures," such as a Grob's Test Mix

[30], to assess column performance. These mixtures generally contain several compounds (e.g., early and late eluters) which are selected to evaluate certain aspects of chromatographic performance, including peak shape and sensitivity. From a practical perspective, the forensic urine drug-testing laboratory may also choose to evaluate acceptable chromatographic performance for selected drug analytes (e.g., amphetamine, phencyclidine, 6-acetylmorphine, codeine) after column installation. Deterioration in performance can then be followed by comparison of the initial chromatogram with subsequent chromatographic data.

III. ASSAY CALIBRATION

The term "*assay calibration*" refers to the process of developing a mathematical model that attempts to predict the value of an independent variable (e.g., concentration) based on the value of the dependent variable (e.g., peak height, peak area ratios). Calibration has sometimes been referred to as inverse prediction or discrimination. This is in contrast to the term "regression," which was described earlier in this paper with respect to linearity of the analytical method. *Regression* refers to a functional relationship between two or more correlated variables [6,21]. In forensic urine drug-testing laboratories, assay calibration is necessary to determine whether an analyte is present in an unknown sample at or above a pre-established administrative cutoff value, as well as to determine the accurate quantitative concentration of the analyte under certain circumstances [72]. Currently, it is most common to calibrate the assay for quantitative measurement using a single, abundant ion fragment that is characteristic of the analyte of interest. Additional ions, referred to as qualifying ions, are used to support the qualitative identification of the analyte in the unknown sample.

Three approaches to assay calibration are commonly utilized in forensic urine drug-testing laboratories: multi-point calibration curves, single-point calibration curves,

and historical calibration curves. The first and probably the most widely employed method of calibration is the preparation of a *multi-point calibration curve*. Experimentally derived multi-point calibration curves are used to cover the concentration range of the samples to be measured, thereby improving the confidence limits associated with the calibration itself. Calibration samples (standards) are prepared from mixtures of different amounts of known concentration of analyte with a fixed amount of internal standard. Specific ion-abundances are measured for the analyte and internal standard, a ratio calculated, and a calibration curve generated using a simple least squares regression model, for example. If the laboratory elects to use a multi-point calibration curve, it must include calibrators that bracket the cutoff concentration. Although many laboratories include a calibrator at the cutoff concentration, it is not required [72].

The calculated concentration of all standards utilized to construct the calibration curve should be within $\pm 20\%$ of their respective target concentrations. If more than three standards are utilized to construct a calibration curve, it is permissible to delete one calibrator for cause (e.g., poor recovery) provided it is not a calibrator at the cutoff concentration. It is not acceptable to eliminate a calibration point solely in order to bring the quality control results within range, although there is some disagreement on this issue since one might expect that the probability of detecting/obtaining an "outlier" will increase as the number of calibrators analyzed in a batch increases [15,72].

Evaluation criteria for linearity of the multi-point calibration curve include the correlation coefficient (r), coefficient of determination (R^2), the slope (m), y-intercept (b), and quantitative value of each data point. The *correlation coefficient* is a measure of the intensity of association between two variables, X and Y . In calibration, the correlation coefficient ranges from 0 to 1; 0 indicates no correlation and 1 indicates a perfect correlation. A correlation coefficient may indicate a high degree of relation between variables, but the generated model (regression equation) may give an inadequate fit for the data. In contrast, the *coefficient of determination* is a measure of "goodness of fit" and is the proportion of variation in the data explained by the regression model. It also ranges from 0 to 1, with 0 indicating a complete lack of fit and 1 indicating a perfect fit. Generally accepted criteria for acceptable linearity using deuterated internal standards for calibration include a correlation coefficient and/or coefficient of determination of at least 0.990, and a y-intercept close to zero, although slightly positive or negative y-intercept values are also acceptable. Because of the potential for negative and positive bias, y-intercept

Figure 1. Theoretical chromatographic peak.

values should be monitored on a regular basis and tracked for development of trends.

For assay calibration, the laboratory must also establish whether the regression line will be forced through the origin (a "no-intercept" model) or will not be forced through the origin (an "intercept" model). In the intercept model, R^2 is the proportion of variance explained by the model. In contrast, R^2 produced by the no-intercept model is a measure of the degree of dispersion around zero and describes the proportion of variance around zero explained by the model [7]. Most GC/MS software programs allow for the user to select between these two approaches. The selection of the appropriate model to be used for a particular assay will depend on several factors, including the type and sensitivity of instrument, the analytical method, the method of ionization, the required analyte detection, and reporting limits. As a general rule, it has been suggested that one should assume that an intercept model is correct until proven otherwise via statistical testing of the intercept [6-8,14]. If statistical testing of the intercept indicates that it is not different from zero (e.g., $b = 0$), then the no-intercept model is appropriate and should be used. However, selection of a no-intercept model implies that the assay limit of detection is zero, which is not the case for GC/MS urine drug-testing assays due to instrument and matrix background effects. Therefore, in most instances regression through the origin should not be used in assay calibration.

The second most commonly employed approach to assay calibration is a *single-point calibration*. In this case, a single standard containing analyte at the assay cutoff concentration is used to establish the cutoff concentration in order to determine whether a specimen is positive or negative. Laboratories then include quality control materials at concentrations below, at, and above the cutoff concentration to demonstrate linearity. The quantitative results for the quality control samples used in single-point calibration must fall within $\pm 20\%$ of their respective target concentrations.

The third approach to assay calibration uses construction of a *historical multi-point calibration curve*. The laboratory establishes the calibration (as above) and verifies that the calibration has not changed between batches via analysis of control samples, one of which is at the cutoff concentration. Use of historical calibration curves is acceptable only if the laboratory has demonstrated linearity and precision of the calibration curve over time. If shifts in response ratios are observed or new internal standard materials are employed, a new standard curve must be prepared. In addition, all batches must include at a minimum a blank and two controls, one at or near the cutoff.

During assay calibration, the laboratory also establishes acceptance ranges for retention time and ion ratios. These acceptance ranges are then used to evaluate each calibrator, control, and unknown specimen in the batch (see Section V). For single-point calibration assays, the acceptable limits are determined from the calibrator at the cutoff. For multi-point or historical calibration curves, acceptable limits may be determined from either the calibrator at the cutoff or from the average of all the calibrators analyzed. If historical calibration curves are used, verification of correct retention time and ion ratios is performed by examination of the "at or near cutoff" quality control sample. In this case, the retention time and ion ratios of this sample must fall within the ranges established by the historical curve, or the assay must be recalibrated [72]. Any of the approaches for determining retention time and ion ratio criteria discussed above are considered acceptable; however, the laboratory must apply the acceptable ranges consistently to all calibrators, controls, and specimens in the batch.

IV. QUALITY CONTROL

A. Required Quality Control Samples

Each assay batch must include a minimum total of 10% open and blind positive and negative quality control samples in an appropriate urine matrix [70]. External blind quality control samples are not required, but are highly recommended. Quality control samples may be purchased commercially or prepared from a different source or lot of standard material other than that used to prepare calibrators. The use of different sources and lot numbers is recommended in order to eliminate systematic quantitative bias in the GC/MS assay that may otherwise go undetected. However, at a minimum, quality control materials should be prepared using standard material prepared from a different weighing or vial of source material other than that used to prepare the calibrators. The target concentration of at least one control must be within approximately 125% of the cutoff concentration; other controls should be prepared at appropriate concentrations in order to regularly assess accuracy below and/or above the assay cutoff concentration. It is recommended that a highly concentrated control sample be diluted in a similar manner as diluted specimens during aliquoting in order to verify the accuracy of the dilution technique, if one is routinely used to prepare presumptive positive specimens for confirmation [72].

In order to evaluate the efficiency of the hydrolysis process, cannabinoid and opiate control samples containing conjugated 11-nor- Δ^9 -tetrahydrocannabinol-9-car-

boxylic acid and morphine, respectively, should be assayed. Negative urine samples spiked with these reference materials can be prepared, or as an alternative, hydrolysis control samples can be prepared from a combined urine pool of previously confirmed specimens. (It is not acceptable to use regulated specimens for this or any other purpose until after completion of the required storage time.)

Finally, it is highly recommended, but not required, that the laboratory use quality control materials that include the addition of potentially interfering substances in its GC/MS assays. These might include compounds that are structurally related to the analyte of interest, or closely eluting compounds. For example, the laboratory may choose to include a control containing hydrocodone, hydromorphone, or oxycodone in its opiate assay to demonstrate that codeine and morphine are correctly identified and accurately quantitated in the presence of potential interferents. Another example is that of the inclusion of a control containing phenylpropanolamine, ephedrine, phentermine, and/or pseudoephedrine in GC/MS assays that utilize a periodate procedure.

B. Verification of Quality Control Materials

Prior to the use of reference materials to prepare calibrator, control, or internal standard material in the laboratory, the laboratory is required to verify, *independently* from the supplier, that its chemical identity is correct and that it is of acceptable purity and concentration. The laboratory may perform this verification itself, or may refer it to another laboratory. At a minimum, most laboratories perform a full-scan GC/MS analysis to verify the chemical identity and purity of the material and compare the obtained spectra with that of available library spectra to determine that significant impurities are not present in the material which might interfere with the method. The appropriate derivatization procedure for the analyte of interest is employed, as well as the GC conditions routinely used for the assay.

The isotopic purity of the internal standard can also be verified with the same procedure described above. In addition to full-scan analysis, the laboratory may also evaluate the deuterated internal standard in selected-ion monitoring (SIM) mode prior to use.

Additional methods for verification of chemical identity and purity may involve measurement of physical constants, such as melting point or refractive index, as well as use of other analytical techniques (HPLC, IR, NMR, TLC, or UV/VIS) to detect nonpolar or nonvolatile impurities [63]. Verification of concentration is most often evaluated indirectly by preparation of calibrators or

controls at known concentrations and analysis in routine batches.

The laboratory must establish specific evaluation criteria for reference materials, such as spectral match requirements, percent isotopic purity required, and quantitative results. The laboratory must retain documentation of all verification procedures performed [72]. The laboratory may then use the reference material to prepare calibrators for controls for routine use. Of course, these new calibrators and controls must then be themselves validated for concentration (e.g., $\pm 20\%$ of the target concentration) prior to routine use.

C. Evaluation of Quality Control Results

There are two major approaches to evaluation of quality control results applied to urine drug testing. The first approach is the use of a fixed-criterion quantitative acceptance range. In this case, the measured concentration of control samples must be within $\pm 20\%$ of the target concentration. A more detailed discussion of the rationale underlying this criterion has already been discussed in Section I-B.

The second approach is to use modifications of Westgard Quality Control Rules to evaluate results. In this approach, the laboratory establishes warning limits and out-of-control limits for the assay based upon the validated mean and standard deviation for the control sample. A thorough description of Westgard rules may be found in several sources [15,35,36,75-77]. Westgard rules are usually not directly applicable to GC/MS forensic testing due to the limited number of quality control data points obtained in a batch, the large number of independent variables associated with GC/MS systems, and the acceptance of potentially out-of-range data. However, if *coupled* with a fixed quantitative accuracy requirement of $\pm 20\%$ for control materials, the rules can be extremely useful for the purposes of evaluating the GC/MS assay for development of trends and systematic biases [38]. Also, other approaches to the evaluation of quality control data, including an ANOVA approach, have been described [37,42].

The laboratory's SOP manual must thoroughly describe the quality control evaluation criteria to be used and must include a policy for the required course of corrective action if quality control sample results fail to meet acceptance criteria. In order to assess laboratory performance, all control data, including out-of-limit data, should be recorded in the quality control log in Levey-Jennings or Shewart chart format [15,27,62,72,75-77]. Out-of-limit data should include documentation of required corrective action. It may be acceptable to reinject a quality control

sample one additional time. If the results are still unacceptable, other minimally acceptable protocols include:

1. Reinjection of calibrators, followed by reprocessing of *all* quality control samples and routine specimen data against the new calibration, *if* the time since the last injection is not excessive and the instrument has not been retuned;
2. Reinjection of all calibrators, quality control samples, and routine specimens; and
3. Acceptance of negative test results that are less than the LOD and reextraction of all other specimens in the batch.

V. CRITERIA FOR DESIGNATING A POSITIVE TEST RESULT

A. Chromatographic Criteria

Criteria for designating a positive test result include chromatographic and spectral identification. Chromatographic identification of an analyte requires comparison of the retention time of the specimen with that of a calibrator at the cutoff or the average of multiple calibrators (either approach is considered acceptable). Generally, the retention time of the analyte should be within $\pm 2\%$ of the retention time as established by the calibrator(s) [11-13,72].

B. Ion Ratios

Further, identification of an analyte requires comparison of ion ratios or full spectral data of the unknown with preestablished ion ratios or full-scan mass spectra, respectively. Acceptable ion ratios for the analyte and its corresponding internal standard are usually calculated using ion abundance data obtained for the standard prepared at the cutoff concentration or by determining the mean ion ratios for all calibrators. It has been demonstrated statistically that while full-scan mass spectrometric data provide the maximum confidence for analyte identification, a minimum of three structurally significant ions generated under electron ionization conditions appear to provide adequate information for an identification [12,64]. If the regulated urine drug-testing laboratory uses EI, it is currently required to use a minimum of two ion ratios for identification of the analyte and at least one ion ratio for the internal standard [72]. Of course, CI-generated spectra do not always meet the three-ion criteria because less extensive fragmentation is generally observed with this technique. However, this limitation is offset by the production of high m/z ions characteristic of the analyte and increased specificity with selection of appropriate reagent gases [11,12,26,81].

The ion ratios for the analyte and its corresponding internal standard obtained for the unknown should not differ by more than $\pm 20\%$ of the target ion ratio and acceptance criteria must be uniformly applied to all specimens within the batch [72]. The establishment of this 20% acceptance criteria for ion abundance ratios has been determined to be appropriate based on ion statistics [11-13,64]. Different ion ratio criteria cannot be applied to different specimens, calibrators, or controls within the batch.

C. Mass Spectral Match

To ensure adequate mass spectral match quality for laboratories utilizing full-scan acquisition, unknown mass spectra must be compared with reference spectra, and fit or match quality values must be computed. The laboratory should determine allowable limits of acceptability in accordance with laboratory studies and manufacturer's recommendations (e.g., 950 or greater out of a scale of 1,000). It is known that reference spectra in spectral libraries may at times differ from that obtained from analysis of actual specimens. This may be due to the type of instrument used, the particular algorithms used to generate a match, the number of ions used to establish a match, type of reagent gas, electron energy, or type of derivatization employed, among other factors. Therefore, the laboratory may consider establishing its own spectral library for analytes of interest, providing that manufacturer's specifications continue to be met and that generated spectra do not differ *significantly* from published reference sources.

In addition to spectral match requirements, the signal-to-noise ratio at the apex of the integrated peak of the analyte and its internal standard should be equal to or greater than a minimum of 10:1 at the assay's LOQ.

D. Quantitative Result

Regardless of the detection technique, in order to be designated as positive, the measured concentration of a specimen must be equal to or exceed the established assay cutoff concentration. Quantitative results around the cutoff must be truncated, rather than rounded up to the nearest whole number, so that the statistical bias is toward a "negative" result.

Specimens directed for GC/MS retest analyses are not subject to cutoff concentrations and are reported as reconfirmed if the concentration is equal to or greater than the LOD of the method. The specimen retest must also meet all other criteria for designating a positive test result. Quantitative reports should be provided only upon written request of the Medical Review Officer.

If the specimen concentration exceeds the linearity limits of the assay and the specimen was not diluted accordingly, the report must state: "the concentration of 'analyte' is greater than 'the established linearity limit'." Also, all criteria for designating a positive test result must be satisfied including chromatographic performance, ion ratios, and retention time data.

VI. MISCELLANEOUS FACTORS

A. Data Presentation

Although presentation of GC/MS data is highly variable among laboratories, printouts for all specimens (calibrators, controls, and positive and negative specimens) must include specimen identification information, total ion chromatogram illustrating entire acquisition window, individual selected ion chromatograms drawn to an approximate 0.5-minute window, mass spectrum (if applicable), spectral data including abundance and ion ratios or spectral match, retention time data, and concentration of analyte. In addition, data file name, date and time of injection, and MS operator name are highly desirable. Figures 2 and 3 illustrate typical GC/MS reports for confirmation of benzoylecgonine in urine using the Hewlett-Packard Mass Selective Detector and the Finnigan-MAT Ion Trap Mass Spectrometer, respectively. Further, a summary sheet presented in tabular format including injection sequence and specimen identification information, spectral data, and quantitative results should be prepared for ease of batch review (see Figure 4).

B. Dilution Protocols

Dilution protocols may be developed based upon the relationship of the immunoassay response and the quantitative result. Specimens may be diluted with GC/MS verified negative urine (or possibly purified water) prior to GC/MS confirmation in order to avoid carryover, prevent chromatographic overload, and to obtain acceptable chromatographic results. It is recommended that a quality control sample be diluted in the same manner as any routine specimen to assess the accuracy of the dilution.

A retest specimen may be tested by an immunoassay procedure in order to determine the need for dilution prior to GC/MS analysis. If dilution protocols are routinely applied by the laboratory, these procedures should be clearly described in the laboratory's SOP manual [72].

C. Reinjection of Extracts

Reinjection of specimen extracts may be necessary due to a failed injection or chromatographic overload. The laboratory must stipulate the number of acceptable reinjections (in regulated laboratories, more than one reinjection is generally considered unacceptable) and the maximum time after the end of the batch that reinjection is acceptable. If the reinjection is necessary due to column overload, the laboratory may elect to establish a policy whereby additional reconstitution solvent is added to the extraction vial prior to reinjection. However, such handling must be clearly recorded on laboratory documents, and the laboratory must establish minimum criteria for internal standard signal-to-noise and ion abundance to ensure that results continue to be reliable.

It is unacceptable to continue to reinject or reextract a specimen in order to "force" a negative or positive result. If a specimen fails acceptance criteria it can be reinjected one time and scheduled for re-extraction one time. However, if it continues to fail to meet criteria for the same reason, the specimen must be reported as negative. When reinjections are performed, it is necessary to reinject at least one standard and/or control in order to verify assay performance at the time of the reinjection. All initial and reinjection data, including failed or unacceptable data, must be maintained. Finally, retuning prior to reinjection is not permitted [72].

VII. REVIEW AND EVALUATION OF GC/MS DATA

All data must be thoroughly reviewed by a minimum of two individuals to verify compliance with the methods specified in the laboratory's procedure manual and to identify clerical and/or analytical errors. Batch acceptance criteria include within-range standards and controls and acceptable MS tune, chromatographic performance, ion abundance (adequate signal-to-noise ratio), and ion ratios or mass spectral match quality. Also, the laboratory may choose to monitor the consistency (reproducibility) of the ion abundance for the internal standard to ensure that it has been added appropriately, and at the correct concentration, to each calibrator, control, and unknown in confirmatory analyses. Furthermore, an acceptable calibration curve must be obtained, a lack of carryover must be demonstrated, and chain-of-custody documentation must be in order.

The SOP must also address the handling and reporting of results when duplicate extracts are assayed, or diluted and undiluted extracts are analyzed. Acceptance criteria for duplicates must specify minimum correlation of quan-

End of Batch

Figure 4. GC/MS Batch Summary Review form.

titative results, usually $\pm 20\%$ if both results fall within the assay's linear range. In addition, both of the results must be equal to or greater than the mandated cutoff concentration, although use of the lowest value is recommended. The averaged results or a single value, diluted or undiluted, may be reported if both results meet acceptance criteria, and SOP requirements are consistently applied.

Review of specimen data should include comparison of the initial immunoassay response with the GC/MS result, an evaluation of chromatographic performance including presence of interfering or extraneous peaks, retention time, minimum ion abundance, ion ratios or mass spectral match quality, quantitation, extraction efficiency, potential for carryover, and chain-of-custody documentation.

Bruce A. Goldberger received a B.A. degree in zoology from Drew University (Madison, NJ) and M.S. and Ph.D. degrees in forensic toxicology from the School of Medicine at the University of Maryland in Baltimore (Baltimore, MD). Dr. Goldberger is currently an assistant professor and is director of toxicology in the Diagnostic Referral Laboratories of the Department of Pathology, Immunology, and Laboratory Medicine in the College of Medicine at the University of Florida (Gainesville, FL).

Dr. Goldberger is certified as a Toxicological Chemist by the National Registry in Clinical Chemistry and a Forensic Toxicology Specialist by the American Board of Forensic Toxicology. Dr. Goldberger was an assistant toxicologist and laboratory manager for the State of Maryland's Office of the Chief Medical Examiner and a toxicologist with the National Center for Forensic Science (Baltimore, MD). Dr. Goldberger's studies have included the analysis of alcohol in breath and the measurement of therapeutic and abused drugs in biological tissues. He has published numerous articles related to forensic toxicology and is co-editor (with Ray H. Liu of the University of Alabama at Birmingham) of the *Handbook of Workplace Drug Testing* (American Association for Clinical Chemistry Press: Washington, DC; 1995).

In recognition of his achievements in research in forensic toxicology, Dr. Goldberger was awarded the first annual Irving Sunshine Award from the Toxicology Section of the American Academy of Forensic Sciences (AAFS) in 1988. In addition, he was the 1994 recipient of the American Association for Clinical Chemistry's Outstanding Scientific Achievements by a Young Investigator Award. Dr. Goldberger is an active member of AAFS, American Association for Clinical Chemistry (AACC), National Safety Council's Committee on Alcohol and Other Drugs, and the Society of Forensic Toxicologists (SOFT).

Marilyn A. Huestis received a bachelor's degree in biochemistry from Mount Holyoke (South Hadley, MA), a master's degree in clinical chemistry from the University of New Mexico (Albuquerque, NM), and a doctoral degree in toxicology from the University of Maryland in Baltimore (Baltimore, MD), where she received a full research scholarship. Currently, Dr. Huestis is a senior research scientist at the Addiction Research Center (ARC), National Institute on Drug Abuse (NIDA), National Institute of Health (NIH), where her research interests include: (a) the pharmacokinetics and pharmacodynamics of drugs of abuse in humans, (b) evaluation of the effects of drugs on behavior including correlations of blood levels of drugs and concurrent changes in performance, (c) evaluation and validation of analytical techniques for detection of drugs of abuse in different biological fluids, and (d) medication development projects including the use of buprenorphine as a pharmacotherapeutic agent in opioid dependence. Dr. Huestis is interested in evaluating diverse routes of drug administration and determining the effect of different routes on the abuse liability of drugs, effects on performance, and on the onset, peak, and duration of action of the resultant effects.

Dr. Huestis has been working in the fields of forensic and analytical toxicology and clinical chemistry for more than 20 years. She was chief toxicologist of Nichols Institute's San Diego laboratory from 1983 to 1988, where she directed the emergency toxicology, therapeutic drug monitoring, analytical toxicology, and urine drug-testing operations. Dr. Huestis has published several important papers in the areas of marijuana pharmacokinetics and pharmacodynamics, in the evaluation and validation of immunoassays, and on the use of alternate testing matrices for drug analysis including hair, saliva, and sweat. She was nominated for the research staff fellow award of the ARC for her studies on the pharmacokinetics and pharmacodynamics of marijuana use. She has also been awarded the AAFS Irving Sunshine Award for outstanding research in forensic toxicology in 1992, and was elected to the Phi Kappa Phi Honor Society for outstanding academic achievement.

Goldberger, Huestis, and Wilkins • Quality Control Procedures for GC/MS Forensic Urine Drug Testing

Dr. Huestis is on the Board of Directors of SOFT and currently serves as secretary of this organization. She also is program chair for the Toxicology Section of AAFS, is an active member and former secretary of the California Association of Toxicologists (CAT), serves on the Therapeutic Drug Monitoring and Clinical Toxicology Committee of AACC, and is a member of the International Association of Forensic Toxicology (TIAFT). Dr. Huestis was co-chair of the joint TIAFT/SOFT Joint Congress held in Tampa, FL in 1994.

Diana G. Wilkins received B.S. (1985), M.S. (1988), and Ph.D. (1991) degrees from the University of Utah (Salt Lake City, UT). She is currently assistant director of the Center for Human Toxicology at the University of Utah Health Sciences Center. She concurrently holds a faculty position as research assistant professor in the Department of Pharmacology and Toxicology, College of Pharmacy at the University of Utah.

Previously, Dr. Wilkins served as the quality control/quality assurance manager and senior toxicologist at the Center for Human Toxicology. Her postdoctoral education included training in toxicology and pharmacology, with particular emphasis on drugs of abuse. She currently participates in teaching undergraduate and graduate courses in clinical and analytical toxicology, pharmacology, and statistics for pharmacologic research at the University of Utah. Her research interests include investigation of the disposition of drugs of abuse in human hair and other biological matrices, as well as applications of mass spectrometry in biomedical research. She has obtained a research grant from NIDA to study the application of hair analysis to the monitoring of treatment compliance.

Dr. Wilkins is a laboratory inspector for the National Laboratory Certification Program under the auspices of the Department of Health and Human Services (HHS) and a laboratory assessor for the Standards Council of Canada. Dr. Wilkins was a member of the Drug Testing Advisory Board of the HHS Division of Workplace Performance for the period of 1994–1997. She has also served as an ad hoc member of several NIDA study sections. She belongs to several scientific associations, including AAFS, SOFT, TIAFT, CAT, and the Association for Women in Science.

Hormonal Control of Testicular Function

Figure. Serum luteinizing hormone (mean \pm SEM) prior to and during the administration of testosterone enanthate (100 mg IM q week) to seven normal men. The dotted line represents the lower limit of the normal range. Note that 4 weeks of testosterone administration are required to suppress serum luteinizing hormone release from the pituitary to abnormally low levels (Amory et al, manuscript in preparation).

Effect of multiple oral doses of androgenic anabolic steroids on endurance performance and serum indices of physical stress in healthy male subjects

Abstract Anabolic androgenic steroids (AAS) are doping agents that are mostly used for improvement of strength and muscle hypertrophy. In some sports, athletes reported that the intake of AAS is associated with a better recovery, a higher training load capacity and therefore an increase in physical and mental performances. The purpose of this study was to evaluate, the effect of multiple doses of AAS on different physiological parameters that could indirectly relate the physical state of athletes during a hard endurance training program. In a double blind settings, three groups ($n = 9, 8$ and 8) were orally administered placebo, testosterone undecanoate or 19-norandrostenedione, 12 times during 1 month. Serum biomarkers (creatine kinase, ASAT and urea), serum hormone profiles (testosterone, cortisol and LH) and urinary catecholamines (noradrenalin, adrenalin and dopamine) were evaluated during the treatment. Running performance was assessed before and after the intervention phase by

means of a standardized treadmill test. None of the measured biochemical variables showed significant impact of AAS on physical stress level. Data from exercise testing on submaximal and maximal level did not reveal any performance differences between the three groups or their response to the treatment. In the present study, no effect of multiple oral doses of AAS on endurance performance or bioserum recovery markers was found.

Keywords Anabolic androgenic steroids · Doping · Recovery · Endurance training · Running

Introduction

The main aim of each professional or amateur athlete is to reach his maximal performance. To succeed, athletes need to balance between training loads (intensity and volume) and recovery periods which allow them to optimise their physiological and psychological capacities. Thus, training programs and specially recovery phases have to be well defined in order to avoid a prolonged imbalance that could lead to overreaching and/or overtraining (Halsen and Jeukendrup 2004; Hug et al. 2003; Kuipers and Keizer 1988; Lehmann et al. 1993; Petibois et al. 2002). In increasing the recovery capacities of the organism, the training volumes and intensities can be amplified thus reducing the risk to reach an overtraining state.

Recently, in endurance sports like cycling and athletics, some athletes reported anonymously the use of anabolic steroids, like testosterone and nandrolone, as an efficient exogenous aid to recover more rapidly following intense physical efforts (Hartgens and Kuipers 2004).

The discovery of testosterone has given rise to the synthesis of multiple anabolic steroids (Kenyon et al. 1938). Rapidly, these products as well as testosterone have been used for doping purposes even if their performance-enhancing properties were largely inconclusive for many years (Haupt and Rovere 1984). Nevertheless, since 1980 some authors reported evidences that anabolic androgenic steroids (AAS) are effective in increasing muscle mass and improving strength (Bhasin et al. 1996; Friedl et al. 1991; Hartgens and Kuipers 2004) but the research done on the recovery rate in humans is too limited to draw definite conclusions yet. As recuperation is a physical and mental concept that is quite difficult to measure directly, the few research done in this context studied indirect parameters, like heart rate and serum lactate levels, creatinine, creatine kinase (CK) and aspartate aminotransferase (ASAT), associated with recovery time. Based on these criteria, some authors reported beneficial effects of AAS (Boone et al. 1990; Keul et al. 1976; Rozenek et al. 1990; Tamaki et al. 2001) whereas others found no consequence of AAS on recuperation (Jakob et al. 1988; Urhausen et al. 1989). Through experiments on birds, Alway and Starkweather (1993) suggested that the increased rate of protein synthesis due to AAS administration could be at the origin of a faster recovery from training load. An extrapolation was done from birds to humans without any scientific proofs.

As AAS are still at the origin of the major adverse analytical findings in the world antidoping laboratories (WADA 2005), the aim of the present study was to investigate more precisely the effect of multiple oral doses of testosterone undecanoate, 19-norandrostenedione or placebo on physical stress in male volunteers during a period of endurance training. Regarding ergogenics effects, the two investigated AAS can not be compared with others main AAS like metandienone or stanozolol which effects on muscle development and lean body mass have been clearly proven (Broeder 2003; Hartgens and Kuipers 2004).

Furthermore, we hypothesised that exogenous AAS intake could affect several blood and urinary parameters. Then some biological markers were analysed through the whole protocol in order to detect a potential typical profile of AAS doped athletes versus placebo. Hypothalamus-pituitary axis hormones (testosterone, cortisol, LH, hCG and SHBG) were measured to assess the effect of the administered AAS on blood hormones profile. Cardiac and muscular markers (Troponin I, Myoglobin, ALAT and Creatine Kinase) as well as inflammatory cytokine (IL-6) and catecholamines have been assessed to evaluate the

physiological effects of strenuous exercise in treated and placebo volunteers.

At the same time, running performances were measured through treadmill tests at the beginning and at the end of the protocol in order to put forward a positive global effect of testosterone and/or 19-norandrostenedione on physical adaptations to training.

Materials and methods

Selection of volunteers

The study was conducted at the Swiss Antidoping Laboratory, in Lausanne (Switzerland), after the approval of the protocol by the ethics committee from the Faculty of Medicine (University of Lausanne). Participants were healthy male volunteers from Caucasian origin, aged between 20 and 30, mainly from the Institute of Sports Sciences and Physical Education (University of Lausanne, Switzerland). All subjects practiced sports on a regular base with weekly training times ranging within 4 and 12 h. Thirty volunteers provided informed consent for the participation in the study. These students were not physically dependant on drugs and were instructed not to take any nutritional supplements or steroids 1 year before and during the study, which could affect their metabolism and steroid profile. Volunteers who were prone to hormonal dysfunction, cardiovascular disease, or have used controlled substances or any medication known to affect steroid metabolism were excluded from the study. Participants were evaluated medically (anamnesis and ECG at rest) and psychologically at the beginning of the study, before the treatment period, and at the end of the study in order to monitor their health. The anthropometrical characteristics of the participants as well as their physical level are summarized in Table 1. The fat percentage was determined with a four site (triceps, biceps, subscapular and suprailiac) skinfold measurement (Pongchaiyakul et al. 2005).

Exercise testing

The trial was divided in three phases. During the first part, all subjects performed a medical inclusive test and a running exercise test 1 month prior to the beginning of the treatment period. The exercise test was done on a ELM2 treadmill (Woodway, Weil am Rhein, Germany) where velocity was increased incrementally until subjective exhaustion of the tested subject. The initial workload was 6 km/h and running velocity was increased by 2 km/h at 3 min intervals. Blood lactate

Table 1 Mean anthropometrics values and physical performance (\pm SD) of the three groups at the beginning and at the end of the study

| | Placebo | | 19-Norandrostenedione | | Testosterone | |
|-----------------------------|-----------------|-----------------|-----------------------|-----------------|-----------------|-----------------|
| | Before | After | Before | After | Before | After |
| Age (years) | 24.2 \pm 2.3 | | 22.9 \pm 2.0 | | 24.1 \pm 1.6 | |

| Running speed at IAT (km/h) | 13.3 \pm 1.9 | 14.4 \pm 1.8 | 12.7 \pm 1.5 | 14.0 \pm 0.7 | 13.6 \pm 0.7 | 14.7 \pm 1.2 |

concentrations at the different running velocities was measured with a Lactate Pro (Arkray, Kyoto, Japan) in capillary blood obtained during a 20 s-break after each stage from the hyperaemised earlobe. Heart rate was registered continuously using surface ECG during the last 30 s of each step of the protocol.

Training program

A special software (Ergonizer, Freiburg, Germany) was used for investigator-independent calculation of lactate threshold based on an equalizing SPLINE interpolation procedure (Roecker et al. 1998). As demarcations of intensity, heart rate at the lactate threshold (LT) and the so-called individual anaerobic threshold (IAT) were determined. The LT was taken from the original definition introduced by Wassermann et al. (1999) at the workload that corresponds to the start of the blood lactate concentration increase. IAT was set as the point at a net lactate increase of 1.5 mmol/l above LT (Dickhuth et al. 1991). Four individual training zones for each volunteer were defined based on the heart rate at the IAT as proposed by Roecker et al. (2002). Zone 1 (83–100% of LT) was used as exercise intensity for recovery or warm-up training. Zone 2 and 3 (100% of LT–95% of IAT for zone 2 and 95–101% of IAT for zone 3) determined the training intensity to improve aerobic performance. Training in zone 4 (99–107% of IAT) was used to increase the lactate tolerance (Roecker et al. 1997).

In order to level the performance of all participants, volunteers had to run four times a week at a low intensity included in the first or second training zone, 2 weeks before the first treatment. To manage their training during the protocol, a heart rate monitor (Fitwatch, Sigma Sport, Germany) was lent to the subjects.

Study medication

The second part of the study consisted in the oral intake of 12 placebo, 19-norandrostenedione or testos-

terone undecanoate pills on Monday, Wednesday and Friday between 6.30 and 8 am for 4 weeks (day 1–28). The subjects were randomly distributed in the three groups of ten individuals. The pills were composed of 300 mg of mannitol for placebo group (P group), 100 mg of 19-nor-4-androstenedione and 127 mg of mannitol for 19-norandrostenedione group (N group), 80 mg of testosterone undecanoate and 115 mg of mannitol for testosterone group (T group). Testosterone undecanoate (Dynapharm Distribution, Meyrin, Switzerland) and 19-nor-4-androstenedione (Sigma, St. Louis, MO, USA) were analytical tested by the Pharmacy of the University Hospital (CHUV, Lausanne, Switzerland) that also prepared the pills.

During the same time period, the volunteers were subjected to a strict individual training program (Fig. 1) aimed at improving endurance performance and causing fatigue and designed by expert staff. Meanwhile, all the subjects had to fill in the short version of POMS (Profile of Mood State) in order to assess the psychological profiles (data submitted for publication).

Spot urines were collected before the first pill intake, during the second week of the training period before and after the running sessions, on day 24 before treatment, 4, 8 and 24 h after and 13 days after the last pill intake (Fig. 1). Urines were kept at 4°C until their delivery to the laboratory and then each urine sample was divided into 20 ml flasks and stored at –20°C until extraction and analysis at the laboratory.

Blood analysis

Blood collections consisted in three tubes, one EDTA 2.7 ml and two serum 4.9 and 5.5 ml (Sarstedt AG & Co., Nümbrecht, Germany) withdrawn before the administration of the pill on day 1, 5, 8, 10, 12, 19, 26 and 29 in fasting conditions. The last tube was collected on day 38, i.e. 10 days after the end of the training program. The tubes were kept at 4°C (maximum 2 h) until the arrival at the laboratory. Hemograms were analysed on the EDTA tubes with a Sysmex XT 2000i

Fig. 1 Schematic representation of the main part of the protocol. The pill intakes are shown by the *asterisks*. The daily training program is detailed with the different training zones (*box with dots*, zone 1; *light grey shaded box*, zone 2; *dark grey shaded box*, zone 3 and *black box*, zone 4). The schedule of sampling is depicted on the *right side* (B, blood; U, urine; U24H: urines during 24 h)

(Sysmex Corporation, Kobe, Japan). These samples were then centrifuged 10 min at 1,700 g and plasma distributed in 3 ml polypropylene tubes and stored at -20°C until further analysis.

Serum tubes were directly centrifuged 10 min at 1,700 g and the plasma collected in 3 ml polypropylene tubes and stored at -20°C until analysis. Serum endocrinology parameters (cortisol, testosterone, LH, hCG, SHBG), muscle and cardiac biomarkers (Creatine Kinase, Troponin I, Myoglobine) and inflammatory markers (Interleukine-6) were measured with an Immulite 2000 (DPC Diagnostic Products Corporation, Los Angeles, CA, USA).

Aspartate, alanine aminotransferase (ASAT, ALAT) and urea were obtained from Dade Behring Diagnostics (Düdingen, Switzerland), runned on Dimension® RXL.

Catecholamines analysis

The subjects were asked to collect all their urines during 24 h on day 4, 17, 25 and 32 (U24H, see Fig. 1). Ten millilitres of HCl 5 N (Merck, Darmstadt, Germany) were added in the 3 l containers (Becton Dickinson BD, Franklin Lakes, USA) to stabilize the urines. Two

aliquots were taken in 10 ml urine monovette (Sarstedt AG & Co., Nümbrecht, Germany) and kept frozen at -20°C until analysis. Adrenalin, noradrenalin and dopamine were measured using high performance liquid chromatography (HPLC) with fluorescence detection (LC 240, Perkin Elmer, Boston, MA, USA).

Statistical analysis

All statistical analysis were performed on Matlab® version 6.1.0, with Statistics Toolbox version 3.0. Since distributions of the concentrations under study here are not necessarily normally distributed, a non-parametric one-way analysis of variance (Kruskal–Wallis ANOVA) was used for comparing means or medians between two groups of data. A *t*-test was also used to compare the sample average to a given constant. A significance level of $P = 0.05$ was considered.

Results

General considerations

Thirty male individuals were recruited to take part to this trial. Because of the vigorous training program imposed on the volunteers, five of them retired from the study due to physical problems (articulations and muscles soreness). The values measured on these individuals were not included in the analysis. The final repartition of subjects was 9, 8 and 8 individuals for P, T and N group, respectively. The anthropometrics values (Table 1) showed no statistical difference ($P > 0.05$) between the three groups before and at the end of the protocol.

The spot urines collected during the protocol were analysed for the detection of the endogenous urinary steroids. Isotope ratio mass spectrometry and gas chromatography coupled to mass spectrometry were used to detect variations of the testosterone metabolites compounds (Baume et al. 2006). Nandrolone metabolites (19-norandrosterone and 19-noretiocholanolone) stemming from the metabolism of 19-norandrostenedione (Bricout and Wright 2004) were also quantified in order to support previously published results (Baume et al. 2004) on the nandrolone metabolites pharmacokinetics (manuscript in preparation).

Physical performance

Three weeks before the first study medication, speed, heart rate, serum lactate concentration and exhaustion were determined during standardized treadmill test.

No statistical difference was found between the groups except for lactate I_{AT} and maximal speed between N and T groups ($P_{NT} = 0.02$ and 0.03). Statistical analysis were done on the same parameters established following a second treadmill test performed 10 days after the end of the training program. The results revealed no difference between the three groups ($P > 0.05$).

To put forward a potential beneficial effect of numerous oral doses of AAS on performance, the same physiological parameters were used. The intra-group differences between the post and the pre-treatment treadmill test values were calculated. As depicted in Fig. 2, a significant increase was observed for maximal speed ($\Delta_{\text{max speed}}$) in all groups (t -test for mean = 0; P_P, P_N and $P_T < 0.05$) and for the speed at the I_{AT} ($\Delta_{\text{speed } I_{AT}}$) for the N group. A noteworthy decrease was noted for the serum lactate concentration at the I_{AT} ($\Delta_{\text{lactate } I_{AT}}$) for P and N groups (P_P and $P_N < 0.05$).

Blood analysis

Several serum endocrinology parameters were measured. The time course of cortisol, total testosterone,

LH, T/LH and T/cortisol ratios along the protocol is depicted in Fig. 3. Comparison (Kruskal–Wallis analysis of variance) of values from the first and the last blood samples showed a significant decrease of cortisol for P and N groups ($P = 0.0007$ and $P = 0.0046$) and of total testosterone for the three groups ($P = 0.0041$, $P = 0.046$ and $P = 0.0063$, for P, N and T group, respectively). The T/LH ratio did not vary along the entire study (Kruskal–Wallis ANOVA; $P > 0.05$) but the T/Cortisol ratio increased significantly for the P group ($P = 0.01$). The first value measured before the beginning of treatment was compared to a group of values composed of the samples 2–8 (days 5, 8, 10, 12, 19, 26 and 29; i.e. during the treatment). No significant variation was noted for all the investigated parameters. The results of hCG analysis were mainly below the detection limit of the test used and are therefore not of use for any interpretation.

Cardiac biomarkers were also measured on all blood samples. Figure 4 shows the variations of creatine kinase. Additionally, the time course of ASAT and urea is depicted in same figure. The statistical analysis did not reveal any intragroup difference (Kruskal–Wallis ANOVA; $P > 0.05$). It has to be noticed that the CK data are expressed in ng/ml which is uncommon and

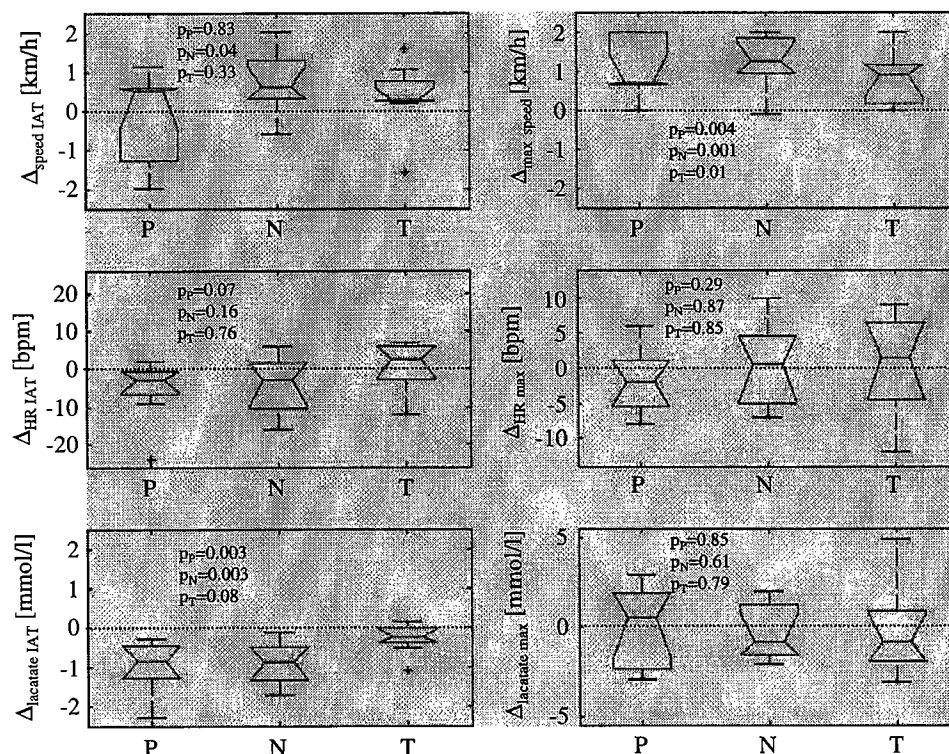

Fig. 2 Individual differences (Δ) between post and pre-treatment speed, heart rate (HR) and lactate values at the individual anaerobic threshold (I_{AT} , left part of the chart) and at exhaustion (max, right part of the chart) for the three groups placebo, 19-norandrostenedione and testosterone. P values indicate the probability of

a significant variation ($P < 0.05$) due to the administered product (i.e. P_T for the testosterone group). The boxes contain 25–75% of the values and the bars illustrate the 95% confidence interval. The median is represented by the line in the boxes. The crosses are the outliers

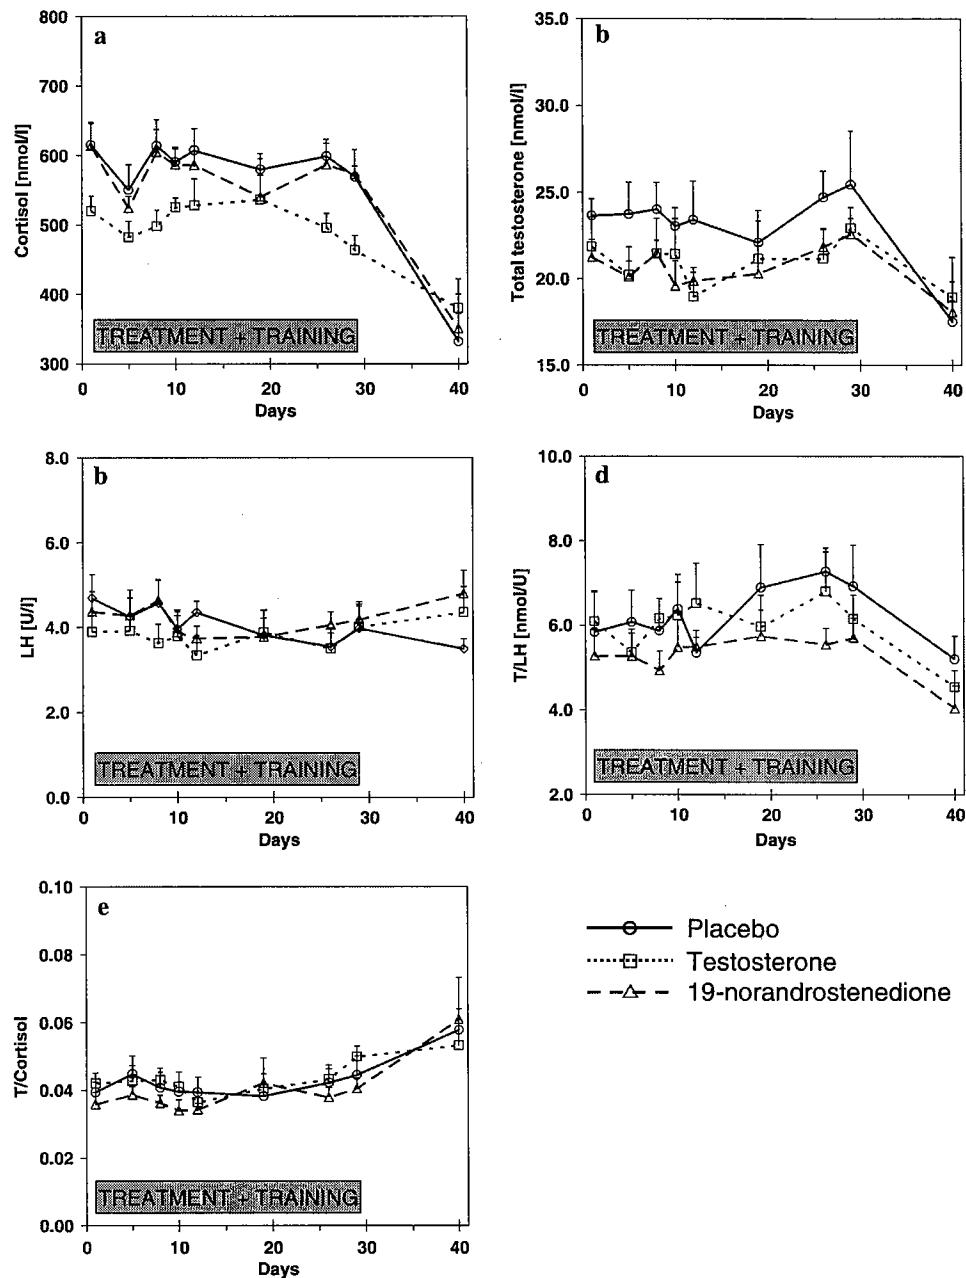

Fig. 3 Values of cortisol (a), total testosterone (b), LH (c), T/LH ratio (d) and T/Cortisol ratio (e) for the placebo (open circles, unbroken line), testosterone (open square, dotted line) and 19-no-

randrostenedione (open triangle, broken line) groups. Values are means \pm SEM. The training and treatment period (28 days, see Fig. 1) is indicated by the shadowed boxes

due to the measurement method. To put the data into perspective, a reference range study revealed a median value of 0.9 ng/ml, an upper 97.5th percentile of 2.6 ng/ml, and an upper 99 percentile of 4.8 ng/ml (Immulate 2000 CK-MB procedure, DPC, CA, USA).

As hCG, the detection of troponine I could not be used because of concentrations ranging below the detection limit of the test used. Myoglobin values remained invariant, the data are therefore not shown.

The blood parameters (full blood count including Hct, Hb, ...) measured on the EDTA tubes revealed no significant variation throughout the trial ($P > 0.05$) (data not shown).

Urinary catecholamines

Four times during the protocol, the volunteers had to collect their urines during 24 h (Fig. 1). The three

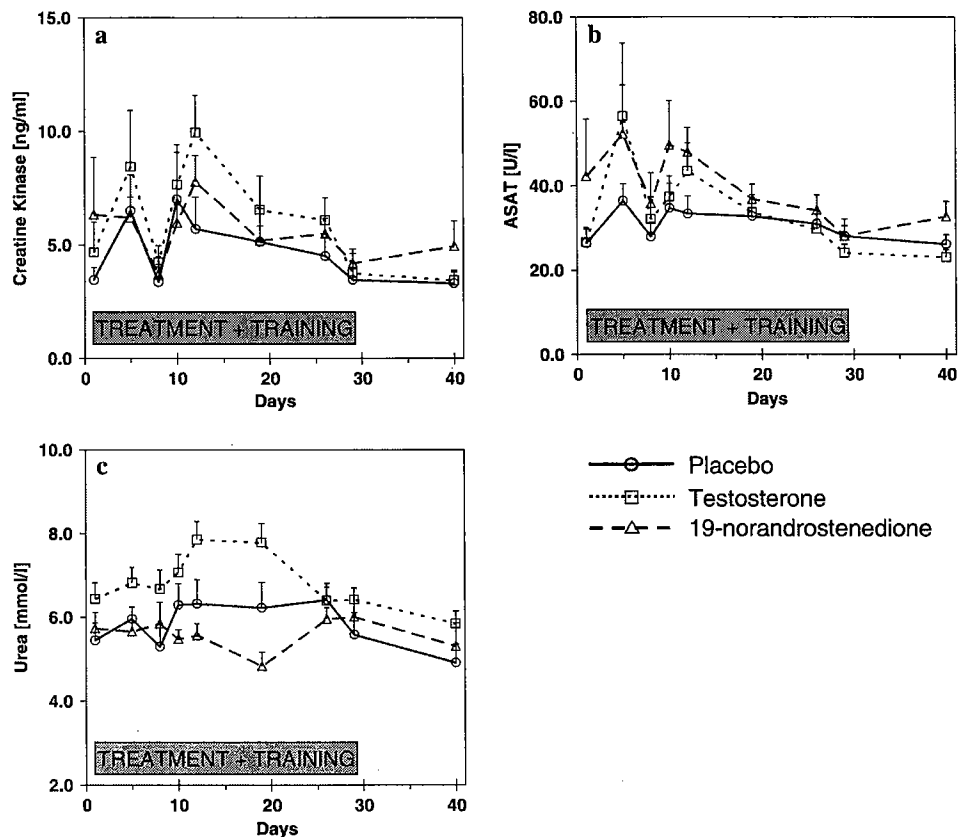

Fig. 4 Values of creatine kinase (a), ASAT (b) and urea (c) for the placebo (open circles, unbroken line), testosterone (open square, dotted line) and 19-norandrosteredione (open triangle,

broken line) groups. Values are means \pm SEM. As in Fig. 3, the training and treatment phase is indicated

major catecholamines, noradrenalin, adrenalin and dopamine were measured. The mean values of the four collection days are depicted in Fig. 5. The values are within the normal range (noradrenalin: 20–80 $\mu\text{g}/24\text{ h}$; adrenalin: 2–20 $\mu\text{g}/24\text{ h}$; dopamine: 190–450 $\mu\text{g}/24\text{ h}$). The only significant difference found during the test was for noradrenalin of the third urine (day 25) between P and T groups with a larger mean value for the T group ($P = 0.0045$).

Discussion

The purpose of this study was to evaluate a potential effect of multiple AAS oral administrations on running performances and on the physical stress level. Up to now, many studies investigated the influence of various AAS on muscular performance and recovery after strength and/or resistance exercise (Bhasin et al. 1996; Kadi 2000; Kuipers et al. 1993). To our knowledge, the endurance factor has never been studied in parallel with a chronic oral intake of testosterone and/or

nandrolone or its precursors. These two products were chosen because they seem to be the AAS most used in sports (WADA 2005). Moreover, oral treatments require an ester of testosterone (Wilson and Griffin 1980) because of the rapid hepatic metabolism of pure testosterone. Norandrosteredione is a recurrent contamination compound of nutritional supplements that are more and more used by athletes. For these reasons, the type of AAS and the doses used in our study could be considered as a good mimical representation of what might be used in professional and amateur sports. Nevertheless, the results of this study may not be directly transferred to all other AAS which could lead to more significant effects.

Exercise tests

To be able to assess a possible beneficial effect of AAS, the training protocol was specifically designed for endurance training based on training regimes used in the preparation of elite athletes and aimed at reaching a high level of physical and mental exhaustion at the

Fig. 5 Mean values (\pm SEM) of urinary excreted noradrenalin (a), adrenalin (b) and dopamine (c) for the placebo (open circles, unbroken line), testosterone (open square, dotted line) and

19-norandrostenedione (open triangle, broken line) groups. The training and treatment period is also depicted

end of the 4 weeks training in the volunteers (Fig. 1). This aim was well achieved according to the oral feedback obtained from the subjects.

For exercise testing, we used a protocol that has been used and validated for the evaluation of running performance in previous studies (Roeker et al. 1998). There are many physiological descriptors for the evaluation of performance. We choose the relation between running speed, serum lactate concentration and heart rate for the description of effort. From these parameters, a reliable prediction of race times in running competitions is possible (Roeker et al. 1998) and thus this test setting has a high practical impact for high performance sport. These three parameters were evaluated at two different time points during the treadmill tests. First, at the IAT and secondly at exhaustion (max) of the subjects. At the beginning of the protocol, only two values were found to be significantly different between N and T groups. T group subjects had a lactate concentration slightly under the one of the N group at the IAT and a maximal speed higher than N group individuals. These points toward the fact that the initial physical

level of the 25 individuals was not uniform and is a recurrent problem in the clinical studies made on human volunteers (Hartgens and Kuipers 2004) that is very difficult to avoid because of the high number of subjects that are required for such studies. Even if these differences exist, in the present study, there are quite negligible ($P = 0.02$ and 0.03). The P, T and N groups were therefore considered as comparable with each other. The variables measured during the treadmill tests performed after the training program (day 38) showed no variation between the three groups ($P > 0.05$) which can be interpreted as an identical intergroup response to training, regardless of the administered substances.

The intragroup performance variation following the training month was assessed in calculating the difference of the same values described above measured during the post and the pre-treatment treadmill tests (Fig. 2). Once again no clear conclusions can be drawn even if $\Delta_{\text{speed IAT}}$ of the N group subjects and $\Delta_{\text{lactate IAT}}$ for N and P groups significantly increased and decreased, respectively. Only one parameter ($\Delta_{\text{max speed}}$)

increased considerably for the three groups. It can be speculated that this increase of the maximal speed might be due to a uniform effect of the training program in the three groups.

On the other hand, there is an adaptation phenomenon of the subjects to the treadmill which implies that an individual will never perform two identical exercise tests. In addition, the intraindividual variation of the performance test might be greater than a potential effect of training or treatment. This is a recurrent problem in sports medicine (Hopkins 2004) and training planning. Therefore the differences observed between the performance related variables at the beginning and the end of the study are not important enough to prove that the investigated oral AAS are useful to increase endurance performance. It has to be noticed that the number of subjects in our study might be insufficient to unmask small effects of AAS. Indeed, it is possible that the performance is influenced by the oral intake of AAS in a range of 2–5%. Such a difference, e.g. in the speed at IAT might have a significant impact in a top level sporting competition but would require higher volunteer number to be revealed.

Hormone profiles

Many authors have investigated the effects of exercise on the endocrine system. While some studies demonstrated that physical efforts do not influence the concentrations of serum hormones like testosterone (Smilios et al. 2003), others clearly showed that there is a hormone variation (testosterone, LH and cortisol) due to exercise (Bonen et al. 1979; Galbo et al. 1977; Kuoppasalmi et al. 1980). These contradictory results could be explained by a reaction dependent on several factors like intensity, duration and mode of exercise and also by the training level of the subjects (Tremblay et al. 2004, 2005; Urhausen et al. 1995; Viru 1992). For this reason, the study protocol is a key criterion to consider before comparing the results reported in the literature. It is well documented that during and just after an endurance effort, testosterone (anabolic hormone) falls under the basal values whereas cortisol (catabolic hormone) concentration increases, which implies a decrease of the anabolic/catabolic (T/cortisol) ratio. It has been suggested that such adaptation allow amino acids to be redirected from protein synthesis to gluconeogenesis needed in stress situation (Duclos et al. 1996; Nindl et al. 2001). Up to now, only the immediate evolution (hours after efforts) of these biological markers has been investigated. With this study we focused on the middle and long-term changes of the hormonal profiles. The hormonal responses depicted in Fig. 3 show no significant

variation for total testosterone, cortisol and LH in the three groups. According to previously reported results (Fernandez-Garcia et al. 2002; Wheeler et al. 1991) a drop of the testosterone serum concentrations should have been observed but none of the three groups showed such picture. Moreover, the intake of testosterone undecanoate seems not to have any effect on the testosterone concentrations meaning that the oral doses were probably not sufficient enough to influence the hypothalamic-pituitary-testicular (HPT) axis. At the end of the training program, the volunteers could be considered as endurance trained athletes. Thus the final decline of testosterone, for the three groups, could be explained by a down regulation of the HPT axis that was already observed in this kind of athletes (Hackney et al. 1990, 1998). Free and bioactive testosterone concentrations were also calculated through the measurement of SHBG (data not shown). As this latter did not vary significantly, the free and bioactive testosterone profiles are the same as the one of total testosterone.

Cortisol has been proven to be one of the essential adaptation hormone during exercise (Viru and Viru 2004) but the variations are dependent of the intensity and duration of effort (Viru et al. 1992). As testosterone, cortisol serum concentration is quite stable during the treatment phase and drops significantly 10 days after the end of the training. The fact that cortisol levels did not change during the training was already observed by Keizer et al. (1989) and this might be explained by the rapid return of this hormone to the basal value. The final decrease of cortisol is probably an indicator of a complete recovery of the volunteers in whom the catabolic activity is not present any more.

Intuitively, longitudinal follow up of athletes during 1 month of endurance training should have resulted in a testosterone decline and then by a retro control feed back to a stimulation of the LH production (Matsumoto and Bremner 1984). As testosterone does not vary, LH remains stable during the entire study. These results have already been reported in the literature. MacConnie et al. (1986) stipulated that this non response of LH may be caused by the prolonged, repetitive elevations of gonadal steroids and other hormones known to suppress gonadotropin-releasing hormone secretion that are elicited by daily exercise. The T/LH serum and urinary ratios have been proven as an indicator of high injection dose of testosterone administration (Kicman et al. 1990). The multiple oral doses of testosterone undecanoate taken by the T groups subjects seem not be sufficient to have a significant impact on the HPT axis as testosterone and T/LH ratio are rather constant and not different from the two other groups, along the study.

All these results could indicate that the HPT axis has not been influenced by the duration (1 month) and intensity of the efforts. As the subjects trained outdoor, the conditions were not controlled as well as in laboratory settings. Nevertheless, the volunteers had to report their daily exercise (time of run and intensities) in order to allow a control of the protocol by the investigators. Except this control, the diet and others physical activities were not monitored. This is probably not an explanation of the relative hormonal stability which is most likely explained by the times of the blood withdrawals (between 6.30 and 8 am, 48 h after the previous medication).

Muscular activity biomarkers

To have an indirect measurement of the physical stress, the global time course of CK, ASAT and urea was assessed during the training month (Fig. 4). CK is an enzyme important for the muscular contraction cycle and present in striated and cardiac muscles. An augmentation of this biomarker could result from a release of the damaged muscles due to intense physical effort (Ebbeling and Clarkson 1989). The basal values of the three groups are slightly above the reference range values. This observation is common in people practicing sports on a regular base. Even if no statistical changes were observed for CK, the profile indicated that at the end of the two first training weeks (days 5 and 12) the subjects have highly solicited their muscles. On days 19 and 26, relatively low CK serum levels could express the organism adaptation to the training stress. ASAT is also contained in striated muscles and increase as well as CK after strenuous bout of exercise. The profile of ASAT is comparable with the one of the CK and confirms the observations made above. Urea is the final product of the amino acids degradation. The dosage of serum urea is mainly performed to evaluate the renal function which can be altered by intense physical exercise (Poortmans 1995). Once again, for testosterone group, the profile illustrates the exercise intensity but for N and P groups no clear pattern was detected. In the case of a better physical stress tolerance following the intake of oral AAS, it can be expected that one or more of these three biomarkers that were chosen for an indirect measurement of stress, would be more constant during an intense training program. Our results do not show any intergroup difference in the serum CK, ASAT or urea profiles. Subsequently, no beneficial effects on physical stress could be attributed to oral testosterone undecanoate or norandrostenedione.

Inflammatory and stress markers

IL-6 has been proven to be an inflammation responsive cytokine that drastically increase after strenuous exercise (Pedersen et al. 1998) and also after prolonged running (Ostrowski et al. 1999). Some authors postulated that IL-6 could be involved in hormonal response to training (Steensberg et al. 2003; Steinacker et al. 2004). The main part of IL-6 analysis performed on the serum samples were below the detection limit of the immunological test used and no statistical interpretation was possible. According to these results, we are not able to confirm an increase of IL-6 for both groups and this parameter seems therefore not useful for a long-term stress evaluation.

To have an indirect feed back of the physiological stress generated by the hard training, catecholamines were quantified in 24 h collected urines (Fig. 5). These are hormones secreted in stress situations. Changes in resting plasma and/or urinary catecholamines (adrenalin and noradrenalin) have been suggested as possible tools for monitoring the impact of training load and/or overload (Lehmann et al. 1997; Mackinnon et al. 1997). It has also been shown that excretion of catecholamines is correlated with training load (Atlaoui et al. 2006) and emotional stress (Lehmann et al. 1988). Between the three measured catecholamines, only noradrenalin seems to be influenced by effort as an increase is observed for the T group. Even if this is a significant change, no reasonable explanation was found.

Limitations

Some limitations must be taken into consideration. First, the fact that training and treatment are done at the same time complicated the interpretation of the results. Second, the statistical models used are of limited significance for a small number of volunteers. More subjects could have unmasked differences in a range of 2–5%. However, small differences would be of great importance for professional athletes that compete at the highest level. Our observations are not in accordance with the major studies made in the field of physical stress and hormone response following endurance exercise, probably because contrasting most other studies, we tried to investigate the development of hormones and other physiological markers in a time period of days rather than hours. The authors estimate that the training intensity and volume were sufficient to trigger typical hormonal responses. Third, the doses of AAS administered in our investigation could have been too low to observe any performance or recovery improvements. However,

our doses were supposed to mimic the ones taken by athletes and higher amounts would not be realistic in the antidoping field. Maybe that a prolonged medication period could lead to statistical differences regarding the investigated physiological parameters between AAS groups and placebo. The effect of AAS could also be psychological and, in that case might not be measurable through physiological parameters.

Conclusion

This study investigated the effect of multiple oral AAS intake on performance capacity and markers of physical stress of endurance trained athletes. Based on the results, it is not obvious that a regular exogenous supply of testosterone undecanoate or 19-norandrostenedione (a nandrolone precursor) reduces physical stress or improves endurance performance of the athlete.

According to these observations, further investigations with higher number of subjects and different treatment times are needed to support the hypothesis that AAS have a real impact on the organism to improve recovery during and after endurance efforts.

Acknowledgements We would like to acknowledge the Federal Office of Sports (BASPO) of Switzerland which provided the financial support for this study and also the 30 participants coming mainly from the Institute of Sport Sciences and Physical Education (ISSEP, University of Lausanne). The authors are also grateful towards Mr Rodolphe Gerber from Bühlmann Laboratories AG (Schönenbuch, Switzerland), Polyanalytic SA (Morges, Switzerland) and the department of sport medicine of the clinical University of Freiburg (Germany) for their technical support for the blood and urine sample analysis. The investigators are thankful towards Sigma Sport (Germany) for having lent the heart rate monitors (Fitwatch).

Abstract

To investigate (1) the effects of exogenous testosterone (T) on self- and partner-reported aggression and mood and (2) the role of trait impulsivity in the T–aggression relationship. Thirty eugonadal men with partners were randomized into two treatment groups to receive: (1) 200 mg im T enanthate weekly for 8 weeks or (2) 200 mg im sodium chloride weekly for 8 weeks. Eight hypogonadal men received 200 mg im T enanthate biweekly for 8 weeks. All groups completed a battery of behavior measures at baseline (Week 0) and at Weeks 4 and 8. Cognitive and motor impulsivity were the only predictors of self-reported total aggression (over and above age and T levels) at Weeks 0, 4, and 8. No significant changes in aggression or mood levels were found in the eugonadal-treated group. Significant reductions in negative mood (tension, anger, and fatigue) followed by an increase in vigor were found in response to T treatment in the hypogonadal group. These results demonstrate that inability to control one's behavior when such control is required by a particular situation (impulsivity) was found to significantly predict levels of aggression over and above age and T level. These data do not support the hypothesis that supraphysiological levels of T (within this range) lead to an increase in self- and partner-reported aggression or mood disturbances. Instead, for the first time, this study has identified the high level of negative affect experienced by hypogonadal patients. These findings have implications for T replacement therapy and male contraception. © 2002 Published by Elsevier Science Inc.

Keywords: Testosterone; Aggression; Hostility; Impulsivity; Hypogonadal; Eugonadal

1. Introduction

The effect of testosterone (T) on behavior, and in particular aggression, has received considerable attention over the last decade [1–4]. This has been prompted by several developments. Firstly, the high-profile media coverage of incidents of 'steroid rage' seemingly associated with the abuse by strength athletes of androgenic–anabolic steroids (AAS) [5]. Secondly, the use of exogenous T clinically as part of the development of a reversible, hormonal contraceptive for men [6], its use for replacement therapy in HIV illness [7], and for treating the psychological and physiological effects of aging in men [8].

In general, these studies can be characterised as: (1) Comparisons between violent criminals and nonviolent controls on some measure of aggression [9–11]. These studies

generally demonstrate higher T levels among the more violent men than the less violent ones. (2) Correlational studies investigating the degree of association among endogenous T levels, aggression, and hostile feelings. These studies have shown conflicting results, with stronger associations being found when behavioral and observational measures have been employed compared to trait measures of aggression [9,12,13]. (3) Experimental studies where T levels have been manipulated into the supraphysiological range [1,14–17]. The existing experimental studies have yielded varied results, and they are difficult to interpret owing to differences in experimental manipulations and in the dependent variables.

Here, we examine reports providing measures of direct aggression for baseline or placebo phases, and for phases when levels of T were elevated to supraphysiological levels. We calculated effect sizes (*g*) from the means and standard deviations provided in the papers, for the differences between baseline and T conditions, and for the differences between placebo and T conditions [18]. Su et al. [16]

injected 20 men with placebo, followed by a low dose of methyltestosterone, and then a high-dose methyltestosterone. Their psychological measures were mainly concerned with mood, but included ratings of 'violent feelings' on a visual analogue scale. Comparing baseline with the high-dose phase yielded a value of $g=.28$; comparing baseline with the low-dose phase yielded a value of $g=.09$. However, the authors report trends for an increase in anger and violent feelings in the high-dose group. Yates et al. [17] reported a double-blind study of 31 men involving 100, 250, and 500 mg of T cypionate. For self-ratings on the assault scale of the Buss–Durkee Hostility Inventory (BDHI), values indicated no difference between baseline or placebo and the average of all three doses of T ($g=.08$ for baseline and $g=0$ for placebo). However, values indicating an increase on this scale were found when the ratings were provided by an informant rather than the person himself ($g=.47$ for comparisons with baseline and $g=.17$ for placebo). Pope et al. [15] reported values on a laboratory measure of aggression [the Point Subtraction Aggressive Paradigm (PSAP) by Cherek et al. [19]] for baseline, placebo, and treatment phases for 27 men receiving up to 600 mg T cypionate. The values were $g=.57$ for the baseline comparison and $g=.51$ for the treatment comparison, indicating a rise in aggression following T treatment. Although the Aggression Questionnaire (AQ), the modern version of the BDHI, was used in this study the values presented were aggregates for the four subscales: physical and verbal aggression, hostility, and anger. An initial report based on 8 of the 51 men completing this measure [20] indicated an increase in physical aggression following treatment ($g=.79$), but a much smaller one for verbal aggression ($g=.20$). In the complete sample, the values for the total AQ scores were around zero, indicating no change in this composite measure of direct aggression, hostility, and anger.

Over the three studies, when effect sizes are calculated, there is some evidence for increases in measures of direct aggression following T administration, but this is inconsistent, and nonsignificant in most cases.

Experimental studies have generally not found evidence for a T–anger relationship [1,14,21]. For example, Tricker et al. [1] administered a large supraphysiological dose of T enanthate (600 mg/week) to a sample of healthy men in a double-blind, placebo-controlled fashion and assessed both self-reported and partner-reported mood and anger. Their study failed to detect any effects on angry behavior or mood. More intriguingly, Bjorkqvist et al. [21] found evidence for a placebo effect, where men who received a placebo in a double-blind experiment reported higher scores on self-estimated anger, irritation, impulsivity, and frustration than those receiving T orally (Panteston). These increases were also supported by the observer estimates. However, these findings should be interpreted with caution given that the orally administered T did not increase circulating T levels into the supraphysiological range.

One concern in this area [21] is that positive results are more readily reported than null ones and that investigators are less likely to submit manuscripts that accept null hypotheses. These findings also suggest that the relationship between T (or steroid use) and aggressive behavior may not be a direct, causal one. With this in mind, it is important to note that few experimental studies have investigated the possible role of individual difference variables, such as impulsivity, in their experimental paradigms [3]. Research in this area is also limited by over-reliance on self-report data, with few studies incorporating observations from a partner or significant other (e.g. Ref. [1]). There is also a dearth of controlled investigations of the effects of T administration on aggressive, hostile behavior, and mood in young hypogonadal men who have low levels of T [22].

The aim of this study was to investigate the dose–response relationship among T levels, behavior, and mood in men. A eugonadal-treated group receiving weekly injections of supraphysiological levels of T and a hypogonadal group receiving physiological replacement levels of T were compared with a eugonadal-placebo control group, over an 8-week period. To improve on previous studies, a wide range of measures were used, including self- and partner-reported aggression, anger and hostility, self-esteem, assertiveness, irritability, and moods. Trait impulsivity was also assessed at baseline.

2. Method

2.1. Subjects

Thirty healthy male volunteers (mean age = 28.2 years; range 19–45 years) and 8 hypogonadal male patients (mean age = 30.8 years; range 23–40 years) participated in the study. The eugonadal men were recruited from local radio and newspaper advertisements. The hypogonadal patients were recruited from the Department of Endocrinology, Manchester Royal Infirmary and Hope Hospital, Manchester, UK. The hypogonadal group consisted of three men with Kallmann's syndrome, two with Klinefelter's syndrome, and three who had a bilateral orchidectomy receiving maintenance T replacement for a mean of 5 years (range 0–14 years).

2.2. Design

Volunteers who met the admission criteria after medical screening were randomised into two treatment groups ($n=15$) to receive (1) in the eugonadal-treated group: 200 mg im T enanthate (Cambridge Laboratories, UK) once weekly for 8 weeks or (2) in the eugonadal-placebo group: 200 mg im 0.9% sodium chloride solution weekly for 8 weeks. The eugonadal-treated group received 200 mg T, weekly for two reasons: (a) the pharmacokinetics of this

Table 1

T preparation are well-documented [23] and (b) this dosage has been used successfully in male contraceptive clinical trials [23]. One participant from the eugonadal-treated group had to withdraw from the study before Week 4 for personal reasons unrelated to the study. A wash-out period of 6–8 weeks was required for the hypogonadal group (to allow endogenous T levels to fall to the low hypogonadal range < 6 nmol/l, the normal range being 10–35 nmol/l) before they were admitted to the study. The hypogonadal group received 200 mg im T enanthate biweekly for 8 weeks. No significant age differences were found between the groups [$F(2,35) = 0.97$, ns]. All participants provided written consent. The study was approved by the Central Manchester Research Ethics Committee for Medical Research.

Volunteers completed a battery of validated behavioral scales (see below) at baseline (Week 0) and at Weeks 4 and 8. Mood was assessed weekly. The volunteers completed all the behavioral measures in the privacy of a clinical research room. Blood sampling was performed before receiving intramuscular injection at Weeks 0, 4, and 8. Time of venepuncture was random among the groups, although, generally each participant provided their sample at approximately the same time of day at each of the time points. All plasma samples were stored at -20°C until assay. T was measured using a time-resolved fluoroimmunoassay (AutoDELFIA Testosterone Kit) with an assay sensitivity of 0.4 nmol/l.

2.3. Instruments

The Barratt Impulsivity Scale-11 (BIS-11) [24] was administered at baseline to assess trait impulsivity. There are three subscales: nonplanning impulsivity, cognitive impulsivity, and motor impulsivity.

The AQ [25] was administered to assess aggression levels. There are four subscales: physical aggression, verbal aggression, anger, and hostility. A total aggression score was also calculated by summing the four subscales (and is the main dependent variable in Tables 1 and 2). For the purpose of this prospective study, the AQ, which is general in its referents, and can be characterised as a trait measure, was modified slightly to refer to a specific period in the

recent past (i.e. the last 4 weeks). This made the measure more suitable for measuring within-subject variation.

The Partner Aggression Questionnaire (AQ-P) is an adapted version of the AQ [25,26] where the male respondent's partner is asked to rate their partner in relation to each of the AQ items. Since the hypogonadal patients were generally not involved in long-term sexual relationships, no partner data were collected.

The Aggressive Provocation Questionnaire (APQ) [26] is a measure of aggressive responding. It consists of 21 vignettes that are representations of real provocative situations. The respondent is asked to imagine at this moment: (1) how he would feel in each situation (angry, frustrated, and irritated), measured on a five-point Likert scale and, (2) how he would react to each situation by choosing one of five action alternatives categorised as follows: (1) avoid, (2) no response, (3) anger, (4) assertive behavior, and (5) direct aggression. In the present study, analysis concentrated on the total number of aggressive and assertive options chosen across the 21 vignettes.

The State Self-Esteem Scale [27] consists of 20 items that are concerned with performance, social, and appearance aspects of self-esteem.

The Rathus Assertiveness Schedule [28] consists of 30 items, which are concerned with assessing to what extent the participant is assertive in a range of situations. Again for the purpose of this prospective study, the respondents were

Table 2

Stepwise multiple regression analysis: predicting total aggression scores

| Variable | Predictors | <i>t</i> | β | R^2 | <i>P</i> |
|---------------------------|--------------------------|----------|---------|-------|----------|
| Total aggression (Week 0) | 1. Cognitive impulsivity | 4.11 | .63 | .39 | $< .01$ |
| Total aggression (Week 4) | 1. Cognitive impulsivity | 3.53 | .57 | .32 | $< .01$ |
| | 1. Cognitive impulsivity | 2.44 | .41 | | $< .05$ |
| | 2. Motor impulsivity | 2.09 | .35 | .43 | $< .05$ |
| Change in $R^2 = .11$ | | | | | |
| Total aggression (Week 8) | 1. Cognitive impulsivity | 5.51 | .73 | .54 | $< .01$ |
| | 1. Cognitive impulsivity | 4.32 | .60 | | $< .01$ |
| | 2. Motor impulsivity | 2.11 | .29 | .61 | $< .05$ |
| Change in $R^2 = .07$ | | | | | |

instructed to rate themselves over a specific period in the recent past (i.e. last 4 weeks).

The irritability subscale from the BDHI [29] was adapted to be completed along a five-point scale and respondents were instructed to rate themselves over a specific period in the recent past (i.e. last 4 weeks).

The Profile of Mood States (POMS) [30] consists of 65 adjectives that describe feelings and mood. There are six subscales: tension–anxiety, depression–dejection, anger–hostility, vigor–activity, fatigue–inertia, and confusion–bewilderment. A total mood disturbance score was also calculated by subtracting the vigor–activity subscale score from the total summation of all other scales. The analysis concentrated on the mean score for each 2-week period (e.g. mean for Weeks 1 and 2).

2.4. Data analysis

Descriptive statistics were calculated for each of the variables. Preliminary Pearson's Product–Moment Correlational analysis and stepwise multiple regression were used to investigate the predictive relationship between the independent variables (e.g. T level, age, cognitive, motor, and nonplanning impulsivity scores) and the main dependent variable, total aggression (total aggression score includes the summation of each of the scored subscales from the AQ) at each time point. Two-factor analysis of variance for a mixed design was used to assess performance differences across testing sessions (time factor: Weeks 0, 4, and 8) and between groups (group factor: eugonadal-treated, eugonadal-placebo, and hypogonadal groups) for all dependent variables. Multiple comparisons were also made using Scheffe post hoc tests. All data were analysed using SPSS for Windows Version 9.0.

3. Results

3.1. Testosterone levels

T levels are shown in Fig. 1. Two-factor ANOVA revealed significant main effects for time [$F(2,68)=52.96$, $P<.01$] and group [$F(2,34)=38.99$, $P<.01$], and a significant Time \times Group interaction [$F(4,68)=16.39$, $P<.01$]. Post hoc analyses showed that exogenous T significantly increased T levels from a baseline level of 21.7 ± 1.6 – 34.4 ± 1.7 nmol/l at Week 4 to 38.4 ± 2.1 nmol/l at Week 8 in the eugonadal-treated group. In contrast, T levels of the eugonadal-placebo group did not change from a baseline level of 20.1 ± 1.4 nmol/l (Weeks 4 and 8 = 18.9 ± 1.3 and 20.0 ± 1.8 nmol/l, respectively). The hypogonadal group responded to T treatment with a significant increase into the normal range from a baseline level of 3.8 ± 1.1 – 18.1 ± 1.6 nmol/l at Week 4 to 22.4 ± 2.3 nmol/l at Week 8.

3.2. Trait impulsivity

One-way ANOVA revealed a significant difference between the groups for nonplanning impulsivity [$F(2,35)=2.66$, $P<.05$]. The hypogonadal group reported significantly lower levels of nonplanning impulsivity than the eugonadal-placebo group. Neither cognitive [$F(2,35)=0.89$, ns] or motor [$F(2,35)=1.95$, ns] impulsivity showed significant differences.

3.3. Preliminary correlational analysis

Table 1 shows the correlations between the independent variables (age, T level, and impulsivity) and the main dependent variable, total aggression at Weeks 0, 4, and 8.

Fig. 1. Testosterone levels in all groups at baseline (week 0), week 4 and week 8.

All groups were first entered into the analysis, to provide greater variability in T levels. The analysis was rerun excluding the hypogonadal group.

At Week 0, only three significant correlations were found. Total aggression was negatively associated with T levels ($r = -.41$, $P < .05$) and positively associated with cognitive and motor impulsivity ($r = .60$, $P < .01$; $r = .56$, $P < .01$; respectively). When the hypogonadal group was excluded, only cognitive and motor impulsivity remained significantly correlated with total aggression levels ($r = .63$, $P < .01$; $r = .48$, $P < .05$; respectively). This indicates that higher levels of trait impulsivity are associated with higher levels of self-reported aggression in the eugonadal men.

At Week 4, two significant correlations were found for all participants combined. Again higher cognitive and motor impulsivity were significantly associated with higher levels of self-reported aggression ($r = .53$, $P < .01$; $r = .56$, $P < .01$; respectively). The correlations were similar after excluding the hypogonadal ($r = .57$, $P < .01$; $r = .54$, $P < .05$; respectively). At Week 8, cognitive and motor impulsivity were the only variables to be significantly associated with total aggression in the combined group and with the hypogonadal men omitted (Table 1).

3.4. Stepwise multiple regression analysis

Stepwise regression was used to further investigate the relationship between impulsivity and total aggression. Table 2 shows the results. At Week 0, only cognitive impulsivity emerged from the analysis, explaining 39% of the variance of total aggression scores. Cognitive impulsivity explained 32% of the variance in total aggression at Week 4, with motor impulsivity explaining an additional

11%. Similarly, at Week 8, cognitive impulsivity explained 54% of the variance in total aggression scores with motor impulsivity explaining a further 7%.

3.5. Aggression Questionnaire

Table 3 summarises self- and partner-reported scores on the AQ for each of the groups.

3.5.1. Physical aggression

No significant main effect was found for time [$F(2,68) = 0.61$, ns] or group [$F(2,34) = 1.29$, ns], suggesting that supra-physiological levels of T did not increase physical aggression. There was a slight trend towards a significant Time \times Group interaction [$F(4,68) = 2.05$, $P = .097$], which is likely to be accounted for by the increase in self-reported physical aggression in the hypogonadal group at Week 4. These findings were further endorsed by the partner reports in the eugonadal-treated and eugonadal-placebo groups. No significant main effects were found for time [$F(2,50) = 2.91$, ns], group [$F(1,25) = 0.80$, ns], or the Time \times Group interaction [$F(2,50) = 0.02$, ns].

3.5.2. Verbal aggression

A significant main effect was found for group [$F(2,34) = 3.39$, $P < .05$]. The hypogonadal group reported significantly higher levels of verbal aggression than the eugonadal-placebo group ($P < .05$). Neither main effect for time [$F(2,68) = 1.47$, ns] or the Time \times Group interaction [$F(4,68) = 0.49$, ns] were significant. Again, no significant main effects were found for partner reports, for time [$F(2,50) = 1.88$, ns], group [$F(1,25) = 0.65$, ns], or the Time \times Group interaction [$F(2,50) = 0.65$, ns].

Table 3

Descriptive statistics for self- and partner-reported scores on the aggression questionnaire at Weeks 0, 4, and 8

| Group | Self report | | | Partner report | | |
|----------------------------|--------------|--------------|--------------|----------------|--------------|--------------|
| | Week 0 | Week 4 | Week 8 | Week 0 | Week 4 | Week 8 |
| <i>Physical aggression</i> | | | | | | |
| Eugonadal-treated | 18.36 (1.61) | 19.07 (1.38) | 18.64 (1.77) | 16.29 (1.68) | 19.07 (1.38) | 17.00 (1.68) |
| Eugonadal-placebo | 18.20 (1.39) | 17.13 (1.22) | 18.06 (1.15) | 15.47 (1.13) | 17.13 (1.22) | 15.71 (1.32) |
| Hypogonadal | 19.75 (1.26) | 22.38 (2.03) | 19.75 (1.43) | | | |
| <i>Verbal aggression</i> | | | | | | |
| Eugonadal-treated | 14.07 (0.69) | 14.14 (0.60) | 13.79 (0.72) | 12.64 (1.10) | 12.23 (1.02) | 12.85 (1.05) |
| Eugonadal-placebo | 13.00 (0.74) | 13.66 (0.65) | 12.40 (0.56) | 11.27 (0.97) | 10.43 (1.05) | 10.64 (0.98) |
| Hypogonadal | 16.00 (1.53) | 16.38 (1.49) | 16.13 (1.69) | | | |
| <i>Hostility</i> | | | | | | |
| Eugonadal-treated | 17.11 (1.47) | 16.29 (1.23) | 15.21 (1.23) | 12.79 (1.09) | 13.69 (1.33) | 14.53 (1.34) |
| Eugonadal-placebo | 16.93 (1.08) | 16.00 (1.48) | 15.26 (1.10) | 12.53 (1.02) | 11.64 (0.80) | 11.21 (0.91) |
| Hypogonadal | 25.25 (2.18) | 26.88 (2.61) | 23.43 (2.38) | | | |
| <i>Anger</i> | | | | | | |
| Eugonadal-treated | 16.43 (1.26) | 16.14 (1.21) | 17.50 (0.74) | 14.57 (1.80) | 14.07 (1.72) | 16.46 (1.40) |
| Eugonadal-placebo | 14.93 (1.04) | 14.60 (1.13) | 15.13 (0.67) | 13.33 (1.38) | 12.79 (1.43) | 14.36 (1.12) |
| Hypogonadal | 20.00 (1.91) | 19.38 (1.38) | 19.50 (1.67) | | | |

Standard error of means are given in parentheses.

3.5.3. Hostility

A significant main effect was found for time [$F(2,68) = 4.89$, $P < .01$] and group [$F(2,34) = 11.11$, $P < .01$]. There was no significant Time \times Group interaction [$F(4,68) = 1.31$, ns]. The hypogonadal group reported significantly higher hostility scores than both the eugonadal-placebo and eugonadal-treated groups ($P < .01$). The significant main effect for time is accounted for by the reduced hostility scores in all groups by Weeks 4 and 8 (Week 4: 18.46 vs. Week 8: 17.27, $P < .05$; Week 0: 19.03 vs. Week 8: 17.27, $P < .01$). The partners generally reported lower levels of hostility than their counterparts. However, there were no significant main effects for time [$F(2,50) = 0.04$, ns], group [$F(1,25) = 2.07$, ns], or the Time \times Group interaction [$F(2,50) = 2.13$, ns].

3.5.4. Anger

No significant main effect was found for time [$F(2,68) = 1.96$, ns] or for the Time \times Group interaction [$F(4,68) = 0.83$, ns]. However, a significant main effect was found for group [$F(2,34) = 4.16$, $P < .05$]. The hypogonadal group reported significantly greater levels of anger compared to the eugonadal-placebo group ($P < .05$). For the partners' scores, a significant main effect was found for time [$F(2,50) = 4.69$, $P < .05$] but not for group [$F(1,25) = 2.07$, ns] or for the Time \times Group interaction [$F(2,50) = 0.20$, ns]. A significant increase in partner-reported anger scores from Weeks 4 to 8 accounted for this significant main effect ($t = 3.47$, $P < .01$).

3.6. Aggressive Provocation Questionnaire

3.6.1. Aggressive actions

No significant main effects were found for either time [$F(2,68) = 1.74$, ns] or group [$F(2,34) = 1.21$, ns]. There was a significant Time \times Group interaction [$F(4,68) = 2.70$, $P = .049$], but post hoc comparisons found no significant differences between any of the cells. These findings provide further support for an absence of a T treatment effect on levels of aggression (Table 4).

3.6.2. Assertive actions

There was a significant main effect for time [$F(2,68) = 4.02$, $P < .05$] but no significant effect for group [$F(2,34) = 0.92$, ns] or for the interaction [$F(4,68) = 0.98$, ns]. The main effect for time was explained by a significant increase in assertive actions from Weeks 0 to 4 (11.95 vs. 13.16; $t = 2.71$, $P < .01$). This trend was sustained at Week 8, although it was nonsignificant ($P = .07$), suggesting that the time effect may be accounted for by an overall placebo effect (Table 4).

3.6.3. Irritability
